Lecture – 33
Spin $\frac{1}{2}$ Angular Momentum

Welcome back to the lectures in Chemistry on the Atomic Structure and Chemical Bonding. My name is Mangala Sunder and I am in the Department of Chemistry, Indian Institute of Technology, Madras. And my email coordinates are given here for you to communicate course related inquiries and things like that ok.

Now, this is a continuation of the last lecture on the introduction to angular momentum. And in this lecture let us look at the properties of the Spin Half System Angular Momentum. The electron spin is the most famous example proton spin the nucleus proton also has an spin angular momentum given by the angular momentum magnitude one half. So, this is the purely quantum mechanical spin property that we were studying.

(Refer Slide Time: 01:12)

Commutation relations between the components.

$$\vec{S} = S_x \hat{x} + S_y \hat{y} + S_z \hat{z}$$
$$\vec{L} = L_x \hat{x} + L_y \hat{y} + L_z \hat{z}$$
$$\vec{L} + \vec{S} \quad \vec{J} = J_x \hat{x} + J_y \hat{y} + J_z \hat{z}$$

Now, in the last lecture I think I left with the question the on the commutation of the component commutation relations basically relations of the components relations between the components. I think we were looking at angular momenta with the following notation; S as the spin angular momentum and in the coordinate representation given by three components; S_x, S_y and S_z. The orbital angular momentum also given by the three

coordinates with the corresponding symbols and the total angular momentum which is the sum of L plus S, L and S the sum of L and S is J_x of x plus the corresponding components in the other directions ok.

(Refer Slide Time: 02:26)

The image shows a whiteboard with the following handwritten content:

$$[S_x, S_y] = i\hbar S_z$$

$$[S_y, S_z] = i\hbar S_x \quad \text{Dimensional}$$

$$[S_z, S_x] = i\hbar S_y$$

$$\vec{I} = \left(\frac{\vec{S}}{\hbar} \right) \text{ or } \frac{\vec{L}}{\hbar} \text{ or } \frac{\vec{J}}{\hbar}$$

An arrow points from the word "Dimensional" to the \hbar in the first two equations. The vector \vec{I} is circled in the third equation.

Now, the question that we want to address and also pursue further is the fact that the components S_x , S_y , the commutator between them is given by this relation $i\hbar S_z$. And likewise the commutator of S_y and S_z is given by $i\hbar S_x$ and S_z , S_x commutator is $i\hbar S_y$ ok. These are dimensioned angular momenta, the dimension is there in the \hbar that you use. Therefore, for the logical development of some of the algebraic properties of them let us define an angular momentum without the dimension namely I as S by \hbar or L by \hbar or J by \hbar whichever that we want to deal with ok.

(Refer Slide Time: 03:48)

$$\vec{I} = \frac{\vec{S}}{\hbar} \text{ or } \frac{\vec{L}}{\hbar} \text{ or } \frac{\vec{J}}{\hbar}$$

$$[\hat{I}_x, \hat{I}_y] = i\hat{I}_z, [\hat{I}_y, \hat{I}_z] = i\hat{I}_x, [\hat{I}_z, \hat{I}_x] = i\hat{I}_y$$

We are going to deal with the spin angular momentum and let us define I in such a way that if I is defined without the h bar then it is immediate that the commutator I_x, I_y is $i I_z$ $I_y I_z$ commutator is $i I_x$ and $I_z I_x$ commutator is $i I_y$ ok. We shall use these as the starting point for all the algebraic properties that we study in this lecture ok, now h bar here.

(Refer Slide Time: 04:27)

$$\hat{I}^2 = \hat{I}_x^2 + \hat{I}_y^2 + \hat{I}_z^2 \quad [\hat{I}^2, \hat{I}_x] = 0$$

$$[\hat{I}^2, \hat{I}_y] = 0 \quad [\hat{I}^2, \hat{I}_z] = 0$$

$\uparrow \uparrow \quad \uparrow \uparrow$
 Simultaneous eigenfunction \hat{I}^2, \hat{I}_x or \hat{I}^2, \hat{I}_y

$$\hat{I}^2 |\psi_{1,2}\rangle = \frac{3}{4} |\psi_{1,2}\rangle \quad \text{spin } \frac{1}{2} \text{ angular momentum}$$

$$\hat{I}_z |\psi_1\rangle = \frac{1}{2} |\psi_1\rangle \quad \text{two possible eigenvalues}$$

$$\hat{I}_z |\psi_2\rangle = -\frac{1}{2} |\psi_2\rangle$$

It is important to note that I^2 which is given as the sum of the squares of the components I_x and I_y and I_z . I^2 commutes with all the three components; I^2 commutator I_x is 0, I^2 commutator I_y is 0 and I^2 commutator I_z

commutator is also 0 ok. Therefore because these are operators angular momentum operators and because they commute, it is possible to have simultaneous eigenfunction for the pairs I^2 or I_x or I_y or I_z .

By convention we normally choose the pair of operators for which the eigenfunctions are defined simultaneously as I^2 and I_z . The spin a half angular momentum corresponds to the following property. I^2 acting on this function it is been a half angular momentum corresponds to two possible Eigen values of the I_z operator ok. I_z acting on ψ_1 gives you half ψ_1 and I_z acting on the other eigenfunction ψ_2 gives you minus half ψ_2 .

So, these are the two discrete values for the z component of the spin half angular momentum. And I think we discussed this in Stern Gerlach experiment that was done in the last class last lecture. What about I^2 ? I^2 on ψ_1 and ψ_2 whichever it is ok, gives you the same result namely $I(I+1)$. And I in this case this 1 half therefore, it gives you 3 by 4 on ψ_1 or ψ_2 , it is a same value ok. So, we have a wave function ψ_1, ψ_2 which is defined by the same Eigen value of I^2 into $I(I+1)$ for the operator I^2 , but different Eigen values half and minus half for the I_z operator.

(Refer Slide Time: 07:01)

The image shows a digital whiteboard with handwritten mathematical expressions. At the top, it says $I^2 \rightarrow (I)(I+1)$. Below that, two states are defined: $\psi_1 = \left| \frac{1}{2} \frac{1}{2} \right\rangle$ and $\psi_2 = \left| \frac{1}{2} -\frac{1}{2} \right\rangle$. These are labeled as $|\alpha\rangle$ and $|\beta\rangle$ states respectively. Below the definitions, the actions of the operators I^2 and I_z are listed for both states. For $|\alpha\rangle$: $I^2|\alpha\rangle = \frac{3}{4}|\alpha\rangle$ and $I_z|\alpha\rangle = \frac{1}{2}|\alpha\rangle$. For $|\beta\rangle$: $I^2|\beta\rangle = \frac{3}{4}|\beta\rangle$ and $I_z|\beta\rangle = -\frac{1}{2}|\beta\rangle$. At the bottom, the actions of the x and y components of angular momentum are listed: $I_x|\alpha\rangle, I_x|\beta\rangle$ and $I_y|\alpha\rangle, I_y|\beta\rangle$.

The usual convention is to write ψ_1 with these Eigen values as the descriptors namely the half for the I_z square sorry I^2 the half for the operator I^2 where $I(I+1)$ this one. So, this is half and then the other half is the Eigen value of the I_z

operator. So, ψ_2 will be $\frac{1}{2}$ and $-\frac{1}{2}$. And the convention in text books and in the literature physics literature and also in the chemistry in the NMR and all these subjects, the convention is to write to this as alpha and beta states, spin half states. These are spin half eigenfunctions with the specific properties as I have given here, I^2 on alpha or I^2 on beta gives you $\frac{3}{4}$ alpha or beta I_z or alpha gives you $\frac{1}{2}$ alpha and I_z on beta gives you $-\frac{1}{2}$ beta.

Now, while this is clear what about the action of I_x on alpha, I_x on beta, I_y on alpha, I_y on beta? Because these are the other two spin angular momentum components. And even though they are not simultaneously Eigen I mean alpha and beta are not simultaneously eigenfunctions of I_x and I_y we must know what happens when I_x operates on alpha or I_x operates on beta and likewise I_y on alpha or beta.

(Refer Slide Time: 08:50)

$$I_+ = I_x + iI_y \quad \text{ang. mom. raising operator}$$

$$I_- = I_x - iI_y \quad \text{Lowering operators}$$

$$I_x |\alpha\rangle$$

$$[I_z, I_+] = [I_z, I_x + iI_y] = iI_y + i(-i)I_x = I_x + iI_y = I_+$$

$$(I_z I_+ - I_+ I_z) |\alpha\rangle = I_+ |\alpha\rangle$$

$$I_z [I_+ |\alpha\rangle] - I_+ |\alpha\rangle \frac{1}{2} = I_+ |\alpha\rangle$$

$$I_z [I_+ |\alpha\rangle] = \frac{3}{2} [I_+ |\alpha\rangle]$$

To calculate this there is a very standard method namely to first look up to the commutator, first define a pair of operators called I_+ spin angular momentum raising operators; we will see why it is angular momentum raising operator. And the other one I_- as $I_x - iI_y$ as the lowering operator, you see in a few minutes why this names raising and lowering come in. To calculate the effect of I_x on alpha, let us start with the commutator I_z comma I_+ and then act on the state alpha, but first let us look at the commutator. That is easy to write down because it is I_z comma $I_x + iI_y$ and the commutator of z with the x gives you I_y it gives you iI_y and the commutator of z with I_y

gives you with y gives you minus I_x and for with plus i into minus i I_x , the answer is I_x plus $i I_y$ is equal to I plus \hbar .

Therefore, the action of $I_z I_{\pm}$ on the state α is the same as the action of I_{\pm} on α . And you can write this down immediately as I_z acting on the state obtained by the action of I_{\pm} on α minus I_{\pm} acting on the state obtained by I_z acting on α and that is of course, $\frac{1}{2} \alpha$ is $\frac{1}{2} \alpha$ and that is equal to I_{\pm} on α . Therefore, I_z acting on this state is equal to $\frac{3}{2}$ acting on the same state. What is the state? The state is the state obtained by the action of I_{\pm} on α . Therefore, I_z has an Eigen function ψ which is this which has an Eigen value $\frac{3}{2}$ on ψ .

(Refer Slide Time: 11:37)

The image shows a digital whiteboard with the following handwritten text and equations:

$$I_z \text{ two eigenvalues only } \frac{1}{2} \text{ and } -\frac{1}{2}$$

$$\underline{I_+ |\alpha\rangle} = 0 \quad I_+ |\beta\rangle$$

$$I_z I_+ |\beta\rangle - I_+ I_z |\beta\rangle = I_+ |\beta\rangle$$

$$I_z [I_+ |\beta\rangle] + \frac{1}{2} I_+ |\beta\rangle = I_+ |\beta\rangle$$

$$I_z [] = \frac{1}{2} [] \quad \underline{I_+ |\beta\rangle}$$

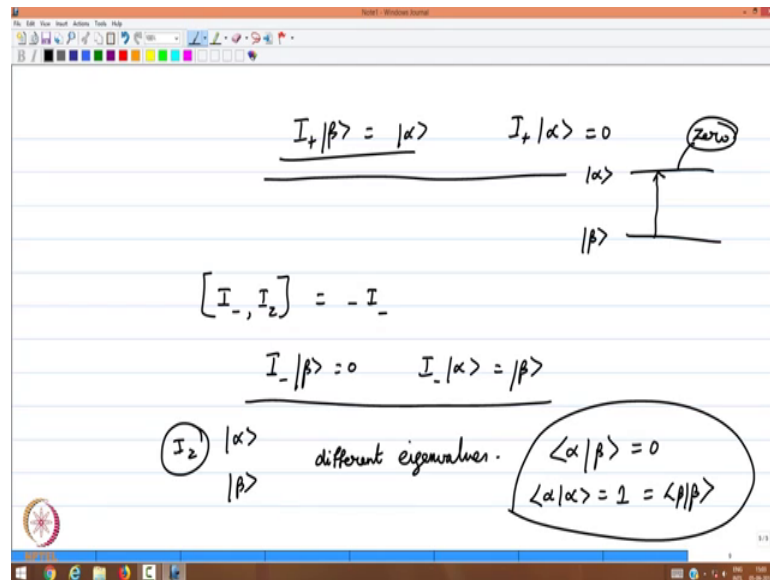

$$I_z |\alpha\rangle = \frac{1}{2} |\alpha\rangle \leftarrow$$

That is not possible because we have started with the requirement with the properties that I_{\pm} has only 2 Eigen values plus and minus half; plus a half and minus a half. Therefore, the state I_z acting on that state giving you $\frac{3}{2}$ the state is not a possible state for the operator I_z , which means I_{\pm} on α has to be 0, it does not exist ok. So, this is property 1. What about the same thing I_{\pm} on β ? You can do the same commutator namely $I_z I_{\pm}$ acting on β minus I_{\pm} acting on β .

It is the same as the I_{\pm} on β and you can see immediately that this gives you a minus half. And therefore, you will get I_z on the state I_{\pm} on β plus $\frac{1}{2}$, I_{\pm} on β you have this size z on β has already given you, $\frac{1}{2}$ times β for what is left over is this and a plus on β on the right hand side which tells you that the two

together gives you I_z acting on a state gives the result of one-half on that state. What is the state? The state is a plus operator acting on beta. Now, remember the eigenfunction of I_z with the Eigen value half is alpha. Therefore, I_+ on beta is equal to this or its proportional to this.

(Refer Slide Time: 13:49)

Linear algebraic calculation tell us that the action of I_+ on beta is alpha, ok. The action of I_+ on alpha is 0. So, if you think of alpha and beta are two states you call this as alpha and you call this as beta. Then you see I_+ acting on the state takes it up and I_+ acting on the state takes in to 0; no further states ok. This is the action of the raising and lowering raising operator on the alpha and beta. The action of the lowering operator be exactly the same argument is obtained by calculating the commutator I_- on I_z and I_- will leave it to you to verify that this is the same as I_- .

And therefore, you will get the relations I_- on beta is 0 I_- on alpha is equal to beta so you have that. Now, also remember that alpha and beta are 2 Eigen states of the I_z operator with different Eigen values. Therefore, the states are orthogonal to each other alpha on beta is equal to 0. The states are normalizable and therefore, we will use only those normalized states namely alpha alpha is 1 and that is equal to beta beta. So, this is the orthogonality property of the Eigen functions of the I_z operator. And the states are such that the action of I_+ and minus operators on alpha or beta or what you have already seen.

(Refer Slide Time: 15:34)

The image shows a whiteboard with handwritten mathematical derivations. At the top left, it says $I_{\pm} |\alpha, \beta\rangle$. To the right, it says $I_x \pm iI_y = I_{\pm}$ with a checkmark. Below this, there are four equations:

$$\checkmark I_x |\alpha\rangle = \frac{1}{2} (I_+ + I_-) |\alpha\rangle = \frac{1}{2} |\beta\rangle$$

$$\checkmark I_x |\beta\rangle = \frac{1}{2} (I_+ + I_-) |\beta\rangle = \frac{1}{2} |\alpha\rangle$$

$$I_y |\alpha\rangle = -\frac{i}{2} (I_+ - I_-) |\alpha\rangle = \frac{i}{2} |\beta\rangle$$

$$I_y |\beta\rangle = -\frac{i}{2} (I_+ - I_-) |\beta\rangle = -\frac{i}{2} |\alpha\rangle$$

On the right side of the whiteboard, there is a note: $I_y = -\frac{i}{2} (I_+ - I_-)$.

Now, therefore, what is I_x on alpha? I_x on alpha is I_+ plus I_- by 2. Remember I_x plus or minus I_y is I_+ or I_- . Therefore, if you add these two you get this I_+ plus I_- is equal to 1 by 2 and therefore, the action of the state on the state alpha by I_x is the same as that. And you know I_+ on alpha is 0 and I_- on alpha gives you beta; therefore, the answer is 1 by 2 beta ok. And I_x in a similar way acting on beta gives you 1 by 2 I_+ plus I_- on beta and I_+ on beta is 0 I_- on beta gives you alpha, therefore, it gives you 1 by 2 alpha.

So, the action of I_x on both the states are known, therefore, the algebraic details are becoming more and more complete, the only other thing that we need to know is the action of I_y on alpha and beta ok. I_y on alpha and beta I can also be obtained in a similar way because you already know the action of plus and minus on alpha. Remember this gives you that I_y is minus i by 2, I_+ minus I_- . If you subtract the one equation from the other this is what you will get. Therefore, I_y acting on alpha is equal to minus i by 2, I_+ minus I_- acting on alpha; I_+ on alpha is 0 I_- on alpha gives you beta.

And there is a minus and minus therefore, it is a plus i by 2 beta. And I_y on beta is again minus i by 2 I_+ minus I_- on beta and I_+ on beta gives you alpha and it gives you minus i by 2 alpha ok. Therefore, summarize these and immediately we can write to

the matrices for these operators in no time here ok. I_x on alpha is half beta, I_x on beta is half alpha, I_y on alpha is i by 2 beta and I_y beta is minus i by 2 alpha.

(Refer Slide Time: 18:19)

The image shows a handwritten derivation on a lined paper background. At the top, two basis states are labeled: $|\alpha\rangle$ and $|\beta\rangle$. Below this, the operator I_x is defined as a 2x2 matrix with elements $\langle\alpha|I_x|\alpha\rangle$, $\langle\alpha|I_x|\beta\rangle$, $\langle\beta|I_x|\alpha\rangle$, and $\langle\beta|I_x|\beta\rangle$. The matrix is shown to be equal to $\frac{1}{2} \begin{pmatrix} 0 & 1 \\ 1 & 0 \end{pmatrix}$. Below this, the Pauli matrix $\sigma_x = \begin{pmatrix} 0 & 1 \\ 1 & 0 \end{pmatrix}$ is identified as the famous Pauli spin-1/2 matrix, x component. Finally, the operator I_y is given as $\frac{1}{2} \begin{pmatrix} 0 & -i \\ i & 0 \end{pmatrix}$, identified as the y component.

Therefore, in this representation of alpha and beta; what is the matrix representation for the operators $I_x I_y$? If you recall the vector algebra and the linear operator space that we did earlier it is alpha I_x alpha this is for the I_x operator and then it is alpha I_x beta and this is beta I_x alpha and this one is beta I_x beta. And you can see right way that alpha I_x on beta is given by this ok. Because this will give you sorry this is for I_y and we have to look at this alpha I_x beta is this one.

So, if you write alpha I_x on beta or this then you do the same thing here 1 by 2 alpha on alpha and this is 1; so the answer is 1 by 2 right. This is 0, I_x on alpha gives you beta therefore, alpha beta is orthogonal. So, you have 0 keeping 1 by 2 outside, you have 110. This matrix sigma x as it is denoted 0110 is the famous Pauli spin matrix spin one-half matrix x component ok.

Likewise for I_y all I need to do is to replace the operator I_x with I_y in all 4 places. And I_y on alpha gives you here, you have seen that gives you beta therefore, this is 0. I_y on beta gives you alpha and therefore, there is you can see that I_y on beta gives you minus I_y 2 times alpha. Therefore, this matrix I_y turns out to be 1 by 2 0 minus i , i 0 ok. And this is again famous Pauli spin matrix half matrix y component ok.

(Refer Slide Time: 20:49)

$$\langle \alpha | I_z | \alpha \rangle = \frac{1}{2} \langle \alpha | \alpha \rangle = \frac{1}{2} \quad \langle \alpha | I_z | \beta \rangle = 0$$
$$\langle \beta | I_z | \alpha \rangle = 0; \quad \langle \beta | I_z | \beta \rangle = -\frac{1}{2}$$
$$I_z = \frac{1}{2} \begin{pmatrix} 1 & 0 \\ 0 & -1 \end{pmatrix} = \begin{pmatrix} 1 & 0 \\ 0 & -1 \end{pmatrix} = \sigma_z$$

z component of Pauli spin $\frac{1}{2}$ matrix

What is a z component? That is easy because I_z on alpha gives you half alpha. Therefore, this element is 1 by 2 alpha alpha and it is 1 by 2. And again alpha on I_z on beta is therefore, 0 because this gives you beta back and orthogonality makes this result equal to 0. And beta I_z on alpha is also 0, beta I_z on beta is minus one half.

So, the matrix representation for I_z is 1 by 2 0 sorry 1 by 2 1 1 0 0 minus 1. This is the sigma z 1 0 0 minus 1 is equal to sigma z, the z component of the Pauli spin matrix, one-half matrix ok. So, these are the properties of the angular momentum operators for a spin half system. Since we know all the spatial components $I_x I_y I_z$ acting on alpha or beta the 2 Eigen states for the problem what they give we have complete knowledge of spin half system with respect to the algebraic details ok.

(Refer Slide Time: 22:29)

The image shows a digital whiteboard with the following handwritten mathematical work:

$$\sigma_x \sigma_y + \sigma_y \sigma_x$$

$$\sigma_x \sigma_y = \begin{pmatrix} 0 & 1 \\ 1 & 0 \end{pmatrix} \begin{pmatrix} 0 & -i \\ i & 0 \end{pmatrix}$$

$$= \begin{pmatrix} i & 0 \\ 0 & -i \end{pmatrix}$$

$$\sigma_y \sigma_x = \begin{pmatrix} 0 & -i \\ i & 0 \end{pmatrix} \begin{pmatrix} 0 & 1 \\ 1 & 0 \end{pmatrix} = \begin{pmatrix} -i & 0 \\ 0 & i \end{pmatrix} = -\sigma_x \sigma_y$$

A large curved arrow points from the first two equations to the result $= 0$.

$$\rightarrow \underline{\underline{\sigma_x \sigma_y - \sigma_y \sigma_x}} = \begin{pmatrix} i & 0 \\ 0 & -i \end{pmatrix} - \begin{pmatrix} -i & 0 \\ 0 & i \end{pmatrix} = 2i \begin{pmatrix} 1 & 0 \\ 0 & -1 \end{pmatrix} = \underline{\underline{2i \sigma_z}}$$

An upward arrow points to the σ_z term in the final result.

Now, to close this lecture you recall in one of the earlier problems we were looking at sigma x, sigma y plus sigma y, sigma x. And you can see right away that sigma x, sigma y, gives you 1 by 4 sorry there is no 1 by 4 this sigma x is just a matrix ok. It gives you 0 1 1 0 and it gives you 0 minus i i 0. The product of which is i 0 0 and minus i and the product sigma y sigma x is 0 minus i i 0 times 0 1 1 0 and that is equal to minus i 0 0 plus i. Therefore, this is equal to minus sigma x sigma y; therefore, this sum is equal to 0. And it is also easy to see therefore, that sigma x, sigma y minus sigma y sigma x is going to take the difference between these two operators namely i 0 0 minus i minus minus i 0 0 i.

So, it gives you 2i times 1 0 0 minus 1; so it gives you 2i sigma z. So, the Pauli spin matrices have a numerical coefficient of two in front of an otherwise a spin angular momentum x or y or z component. So, this is a very famous relation called the Pauli's this famous statement that we have that the Pauli spin operators anti commute, meaning that if you take the plus combination they go to 0 that is the negative of the commutator therefore, it is called and take computation and it is not just x and y or z its cyclical.

(Refer Slide Time: 24:42)

Cyclical : $\sigma_y \sigma_z + \sigma_z \sigma_y = 0$ $\sigma_y \sigma_z - \sigma_z \sigma_y = 2i\sigma_x$
 $\sigma_z \sigma_x + \sigma_x \sigma_z = 0$ $\sigma_z \sigma_x - \sigma_x \sigma_z = 2i\sigma_y$

$$\sigma^2 = \sigma_x^2 + \sigma_y^2 + \sigma_z^2 = \begin{pmatrix} 0 & 1 \\ 1 & 0 \end{pmatrix}^2 + \begin{pmatrix} 0 & -i \\ i & 0 \end{pmatrix}^2 + \begin{pmatrix} 1 & 0 \\ 0 & -1 \end{pmatrix}^2$$

$$= 3 \mathbb{1}_{2 \times 2}$$

$$\sigma^2 = 3 \mathbb{1}_{2 \times 2}$$

Therefore, the similar relations that you can verify are sigma y, sigma z plus sigma z, sigma y that is 0, sigma z, sigma x plus sigma x, sigma z is 0 and sigma y sigma z minus sigma z sigma y is 2 i sigma x and likewise sigma z sigma x minus sigma x sigma z is 2 i sigma y ok. One last thing namely sigma square is sigma x square plus sigma y squared plus sigma z squared and this you know is 0 1 1 0 squared plus 0 minus i i 0 square plus 1 0 0 minus 1 squared, the answer is 2 times here, this will give you 1 this will give you 1, the answer is 3 times the identity matrix 2 by 2 plus this will give you 1 0 0 1. This will give you 1 0 0 1 this would also give you 1 0 0 1. So, it is 3 times the identity matrix.

Therefore, sigma squared is equal to the operator 3 with the identity right. So, these are angular momentum properties that we need to know for us for the half system. And in the next lecture we will see the angular momentum for two such electrons or two such spin half systems, how do we define them, when the two spins interact with each other strongly or when the two spin systems interact with each other weakly. And this is extremely important in establishing what is known as the anti symmetric state for two identical the spin systems of spin half, namely, the electrons as an example or 2 protons.

And this will also just give you some input insights into the famous principle that Pauli came up with namely the Principle for the Anti Symmetry and the principle of what is

called Exclusion, mutual exclusion which is important in the study of atomic structure ok. We will do more of this with the two spins in the next lecture until then.

Thank you very much.
