Lecture - 58
Hydraulic turbine modelling (Contd.)

So, we are back again. So, you have seen that equation 7 regarding your water starting time, right.

(Refer Slide Time: 00:27)

(11)

From Eqns. (2) and (7), we can express the relationship between change in velocity and change in gate position as:

$$T_W \frac{d(\Delta U)}{dt} = 2(\Delta G - \Delta U)$$
$$\therefore S T_W \Delta U = 2(\Delta G - \Delta U)$$

For from equation 2 and 7 we can express the relationship between change in velocity and change in gate position as, right. Therefore, we can write that is from equation 2 and 7, right.

(Refer Slide Time: 00:45)

From Eqns. (2) and (7), we can express the relationship between change in velocity and change in gate position as:

$$T_W \frac{d}{dt} (\Delta U) = 2(\Delta G - \Delta U)$$

$$\therefore S T_W \Delta U = 2(\Delta G - \Delta U)$$

$$\therefore \Delta U = \frac{2}{1 - S T_W} \Delta G$$

So, equation if you look at equation 7, it was your T_W your $\frac{d}{dt}$ of ΔU bar is equal to minus ΔH bar, right. So, from equation 2 substitute for ΔH bar and then you will get the $T_W \frac{d}{dt}$ of ΔU bar is equal to 2 into ΔG bar minus ΔU bar.

(Refer Slide Time: 00:45)

form becomes:

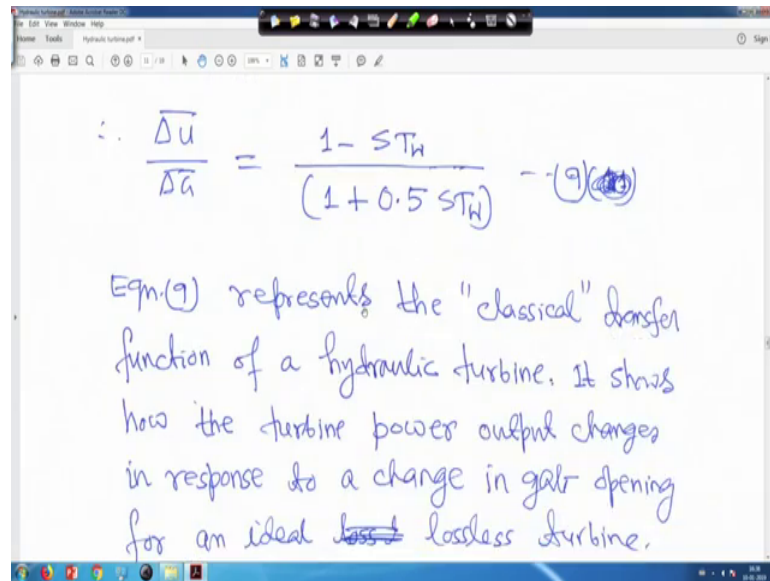

$$\frac{L V_0}{g H_0} \frac{d}{dt} \left(\frac{\Delta U}{u_0} \right) = \frac{-\Delta H}{H_0}$$

$$\therefore T_W \frac{d}{dt} (\Delta U) = -\Delta H \quad \text{--- (7)}$$

Where

If you take Laplace transform it can write left hand side simply we can write $S T_W \Delta U$ bar that function of S not putting again and again because it is understandable is equal to 2 into ΔG bar minus ΔU bar, right.

(Refer Slide Time: 01:21)

The image shows a digital whiteboard with a blue border. At the top, there is a toolbar with various drawing tools. The main content is handwritten in blue ink. It starts with the equation $\therefore \frac{\Delta \bar{u}}{\Delta \bar{a}} = \frac{1 - ST_W}{(1 + 0.5 ST_W)}$ followed by a circled number 9. Below the equation, there is a paragraph of text explaining the equation's significance.

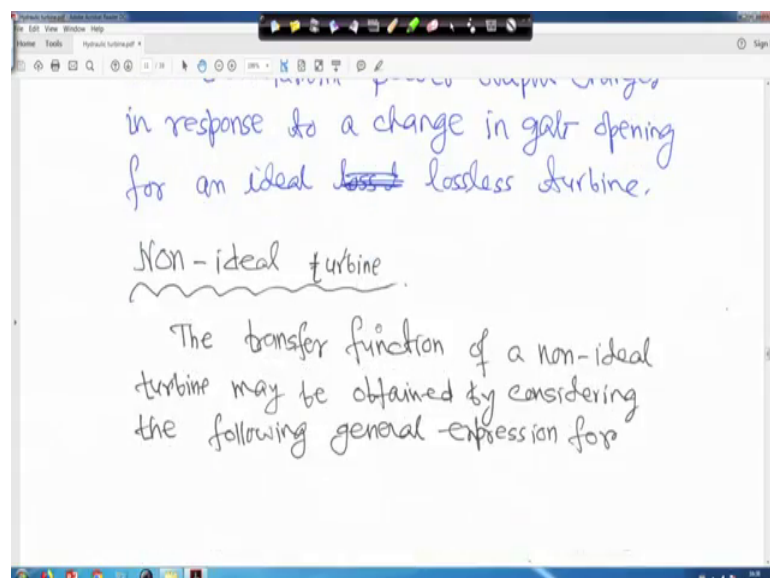

$$\therefore \frac{\Delta \bar{u}}{\Delta \bar{a}} = \frac{1 - ST_W}{(1 + 0.5 ST_W)} \quad \text{--- (9)}$$

Eqn.(9) represents the "classical" transfer function of a hydraulic turbine. It shows how the turbine power output changes in response to a change in gate opening for an ideal ~~loss~~ lossless turbine.

Or $\Delta \bar{u}$ upon $\Delta \bar{G}$ is equal to we can write that $1 - ST_W$ divided by $1 + 0.5 ST_W$, this is equation 9, right. Now, equation 9 actually represent the classical transfer function of a hydraulic turbine, right. It shows how the turbine power output changes in response to a change in gate opening for an ideal lossless turbine, right.

So, this is that your what you call this is the transfer function of the your what you call for a classical model of hydro turbine, right and a transfer function, right. So, for an, so non-ideal turbine so, this is ideal turbine, now say non-ideal turbine.

(Refer Slide Time: 02:09)

The image shows a digital whiteboard with a blue border. The text is handwritten in blue ink. It starts with a paragraph of text, followed by a section header 'Non-ideal turbine' which is underlined with a wavy line. Below that, there is another paragraph of text.

in response to a change in gate opening for an ideal ~~loss~~ lossless turbine.

Non-ideal turbine

The transfer function of a non-ideal turbine may be obtained by considering the following general expression for

Now, the transfer function of a non-ideal turbine may be obtained by considering the following general expression for perturbed values of water velocity that is flow water flow and turbine power.

(Refer Slide Time: 02:19)

(12)

perturbed values of water velocity (flow) and turbine power:

$$\Delta \bar{u} = a_{11} \Delta \bar{H} + a_{12} \Delta \bar{\omega} + a_{13} \Delta \bar{G} \dots (10)$$

$$\Delta \bar{P}_m = a_{21} \Delta \bar{H} + a_{22} \Delta \bar{\omega} + a_{23} \Delta \bar{G} \dots (11)$$

where $\Delta \bar{\omega}$ is the per unit speed deviation

Say it can be written as say $\Delta \bar{u}$ is equal to here actually it is 11, it is a 11, right $\Delta \bar{u}$ is equal to a 11 $\Delta \bar{H}$ plus a 12 $\Delta \bar{\omega}$ plus 13 $\Delta \bar{G}$ bar, right. And $\Delta \bar{P}_m$ a 21 $\Delta \bar{H}$ a 22 $\Delta \bar{\omega}$ bar and plus a 23 $\Delta \bar{G}$ bar, right. So, where $\Delta \bar{\omega}$ is the per units speed deviation, right. So, this actually a 11 by mistake I have written a 1 it is a 11, right.

(Refer Slide Time: 03:05)

$$\bar{\Delta P}_m = a_{21} \bar{\Delta H} + a_{22} \bar{\Delta \omega} + a_{23} \bar{\Delta G} \quad \text{--- (11)}$$

where $\bar{\Delta \omega}$ is the per unit speed deviation. The speed deviations are small, especially when the unit is synchronized to a large system; therefore, the terms related to $\bar{\Delta \omega}$ may be neglected. Consequently,

$$\bar{\Delta P}_m = a_{21} \bar{\Delta H} + a_{23} \bar{\Delta G}$$

So, delta omega bar is the per unit speed deviation. Actually, the speed deviations are very small especially when the unit is synchronised to a large system, right. So, that mean delta omega is almost 0, so we can neglect it.

(Refer Slide Time: 03:25)

related to $\bar{\Delta \omega}$ may be neglected. Consequently,

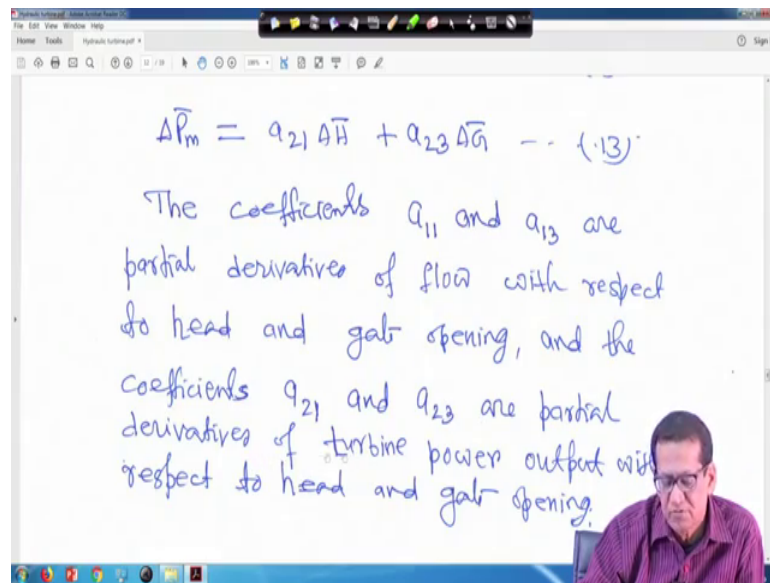

$$\bar{\Delta U} = a_{11} \bar{\Delta H} + a_{13} \bar{\Delta G} \quad \text{--- (12)}$$

$$\bar{\Delta P}_m = a_{21} \bar{\Delta H} + a_{23} \bar{\Delta G} \quad \text{--- (13)}$$

The coefficients a_{11} and a_{13} are partial derivatives of flow with respect to head and gate opening, and

Therefore, the terms related to delta omega bar may be neglected. Consequently you will get delta U bar is equal to a 11 delta H bar plus a 13 delta G bar, right. So, this is equation 12. Similarly, delta P m bar is equal to a 21 delta H bar plus a 23 delta G bar this is equation 13, right.

(Refer Slide Time: 03:45)

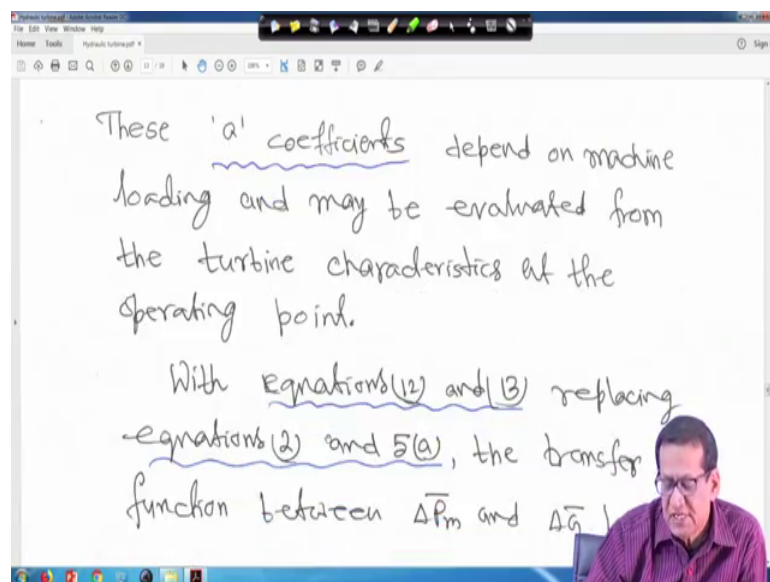

The screenshot shows a whiteboard with the following content:

$$\Delta \bar{P}_m = a_{21} \Delta \bar{H} + a_{23} \Delta \bar{G} \quad \dots (13)$$

The coefficients a_{11} and a_{13} are partial derivatives of flow with respect to head and gate opening, and the coefficients a_{21} and a_{23} are partial derivatives of turbine power output with respect to head and gate opening.

So, the coefficients a_{11} and a_{13} are partial derivative of flow with respect to head and gate opening and the coefficient a_{21} and a_{23} are the partial derivatives of turbine power output with respect to head and gate opening, right.

(Refer Slide Time: 04:05)

The screenshot shows a whiteboard with the following content:

These 'a' coefficients depend on machine loading and may be evaluated from the turbine characteristics at the operating point.

With Equations (12) and (13) replacing Equations (2) and 5(a), the transfer function between $\Delta \bar{P}_m$ and $\Delta \bar{G}$ is

So, this a coefficients depend on machine loading and may be evaluated from the turbine characteristics at the operating point, right. With the equations 12 and 13 replacing equation 2 and 5 a, the transfer function between ΔP_m and ΔG become, it $\Delta P_m / \Delta G$ is equal to $a_{23} / (1 - a_{13}) + a_{11} / (1 - a_{13})$.

into $S T W$ divided by 1 plus $a_{11} S T W$. This is equation 14, right. So, in terms of 'a' coefficient after manipulating this you will get this transfer function, right.

(Refer Slide Time: 04:23)

The 'a' coefficients vary considerably from one turbine type to another. For an ideal lossless Francis type turbine:

$$\frac{\Delta P_m}{\Delta \bar{\omega}} = a_{23} \frac{\left\{ 1 + \left(a_{11} - \frac{a_{13} a_{21}}{a_{23}} \right) s T_H \right\}}{(1 + a_{11} s T_H)} \quad \text{---(14)}$$

$a_{11} = 0.5$; $a_{13} = 1.0$; $a_{21} = 1.5$;
 $a_{23} = 1.0$

The a coefficients vary considerably from turbine type to another, right from I mean from different type of turbine this a value may be different. For an ideal lossless Francis type turbine say a_{11} is equal to 0.5, a_{13} 1, a_{21} 0.5 and a_{23} 1.0, right. It is simply data from somewhere I have taken.

(Refer Slide Time: 05:11)

$a_{11} = 0.5$; $a_{13} = 1.0$; $a_{21} = 1.5$;
 $a_{23} = 1.0$

Typical measured values of the 'a' coefficients for a 40 MW unit with Francis turbine as follows:

Now, typical measured values of the a coefficients for a 40 megawatt unit with Francis

turbine as follows. So, this is some typical measured value I have taken.

(Refer Slide Time: 05:19)

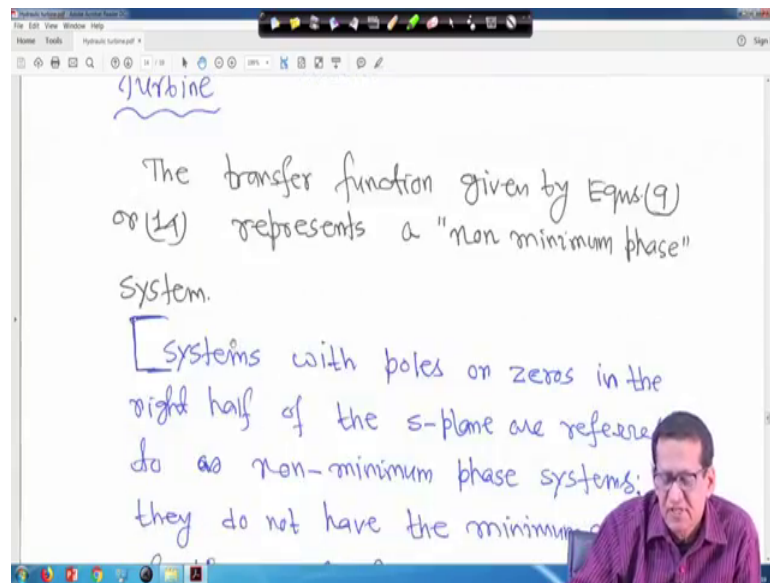

Load level	a_{11}	a_{13}	a_{21}	a_{23}
100% of rated	0.58	1.1	1.40	1.5
No load	0.57	1.1	1.18	1.5

Special Characteristics of Hydraulic

Say load level when 100 percent a 11 is 0.58, but when it is no load it is 0.57. So, more or less a 11 more or less constant, right. Now, load level when you come to a 13 100 percent rate it is 1.1 and that no load it is 1.1, so both two are same, right. Similarly, a 21 so, 100 percent rated 100 percent of rated 1.4, but at no load 1.18.

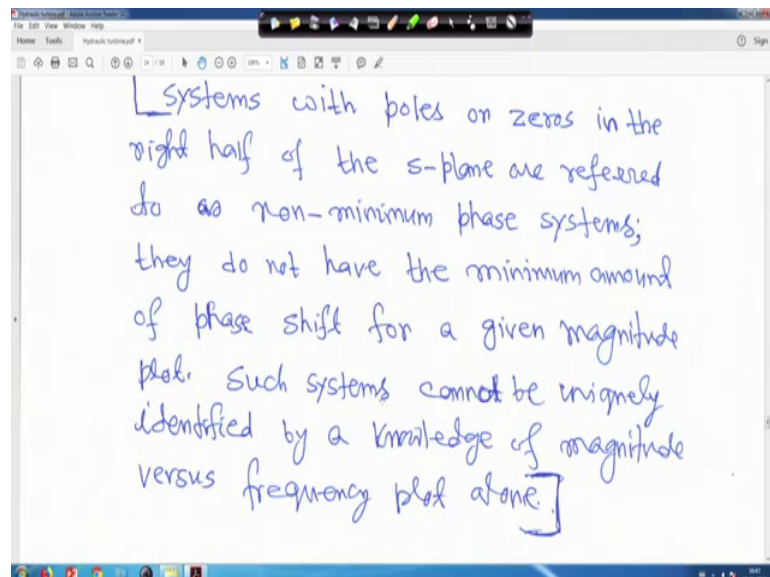

So, this is changing your with the load, right and similarly your a 23 for 100 percent of rated is 1.5 and for no load 1.5. So, only thing is; only thing is that only a 21 actually changing, right about this is also constant, this is also constant this is also more or less constant only a 21 is changing, right.

(Refer Slide Time: 06:19)

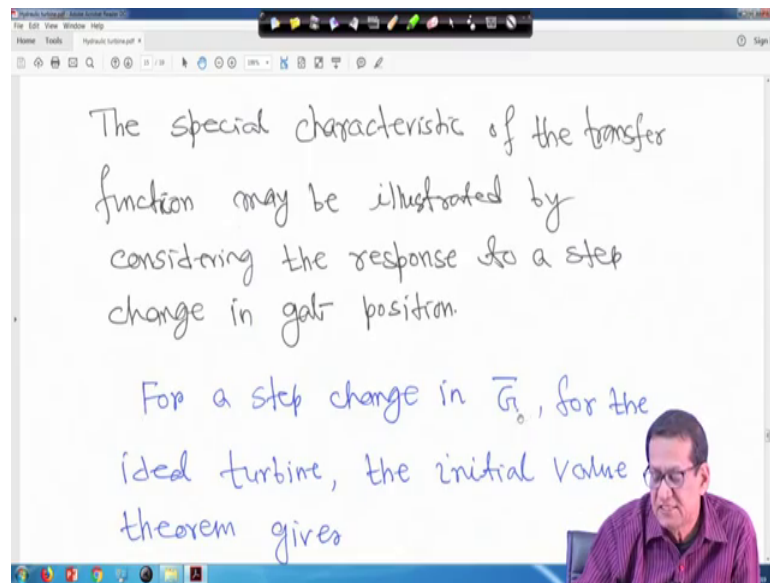

So, special characteristics of hydraulic turbine. The transfer function given by equation 9 or 14 represents a non-minimum phase system. You might have heard this one that is your non-minimum phase system. So, systems with poles or zeros in the, right half of the S plane are referred to as non-minimum phase system, right.

(Refer Slide Time: 06:39)

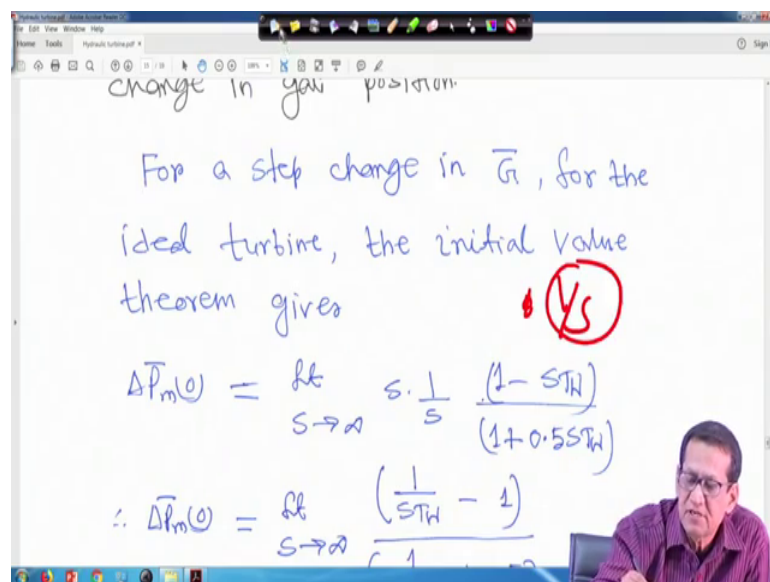

They do not have the minimum amount of phase shift for a given magnitude plot, right. Such systems cannot be uniquely identified by knowledge of magnitude versus frequency plot alone, right.

(Refer Slide Time: 06:53)

So, special your special characteristic of the transfer function may be illustrated by considering the response to step change in gate position, right. For a step change in G bar, for the ideal turbine, the initial value of then your given as, right.

(Refer Slide Time: 07:11)

So, that is actually see if you take a step change; if you take a step change that is your G bar that is ΔG bar we have seen all this thing. So, basically if you take a step change of this one, G bar it will be 1 upon S , right. So, if you just put 1 upon S and you know the limit S tends to infinity means t tends to 0 the initial values. So, S into 1 upon S your 1

minus S T W divided by 1 plus 0.5 S T W, right. So, just let me move little bit half, right.

(Refer Slide Time: 07:49)

$$\Delta P_m(s) = \lim_{s \rightarrow \infty} s \cdot \frac{1}{s} \cdot \frac{(1 - STW)}{(1 + 0.5STW)}$$

$$\therefore \Delta P_m(s) = \lim_{s \rightarrow \infty} \frac{\left(\frac{1}{STW} - 1\right)}{\left(\frac{1}{STW} + 0.5\right)}$$

$$\therefore \Delta P_m(s) = -2.0$$
 and the final value theorem gives

$$\Delta P_m = \Delta P_m(\infty) = \lim_{s \rightarrow 0} s \cdot 1 \cdot \frac{(1 - STW)}{(1 + 0.5STW)}$$

So, numerator and denominator you divide by S T W. So, it will me S S will be cancel, limit S tends to infinity it will be 1 upon S T W minus 1 and this will be 1 upon S T W plus 0.5. So, as S tends to infinity this term is 0, this term is 0, it is minus 1 by 0.5, so basically delta P m point 0 is equal to minus 2, right sorry.

(Refer Slide Time: 08:15)

$$\therefore \Delta P_m(s) = -2.0$$
 and the final value theorem gives

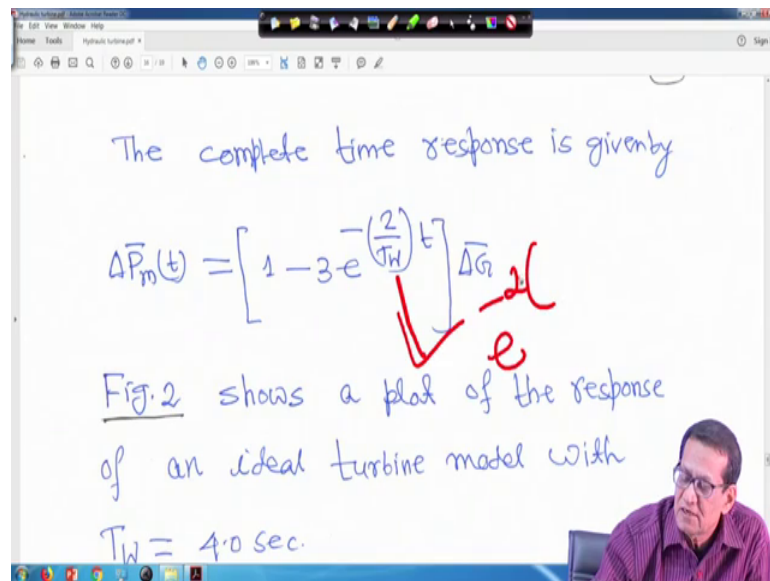

$$\Delta P_{m,ss} = \Delta P_m(\infty) = \lim_{s \rightarrow 0} s \cdot 1 \cdot \frac{(1 - STW)}{(1 + 0.5STW)}$$

$$\therefore \Delta P_{m,ss} = 1.0$$

And the final value theorem is that delta m your P m bar that is steady state value that steady state value is equal to delta P m bar infinity, limit S tends to 0 means that is your t

tends to infinity, right. That is why here it is written your here it is written in $t \rightarrow \infty$ ΔP_m bar infinity that is actually t tends to infinity, the steady state value, so for S tends to 0. So, S will be cancelled, for a step input it is $1 - 3e^{-\frac{t}{T_W}}$ upon $1 + 0.5 \frac{S}{T_W}$. So, if it is 0, so it is basically steady state value it is 1, right. So, what we see that initial value is negative your $\Delta P_m(0)$ is equal to minus 2 here and final value that is your 1.0 the steady state value, right.

(Refer Slide Time: 09:09)

So, the complete time response for a step infinity if you take it will be ΔP_m bar t is equal to $1 - 3e^{-\frac{t}{T_W}}$ ΔG , right. So, this is actually your what you call that your final your what you call that your because that is time function, right. So, this little bit you can do it.

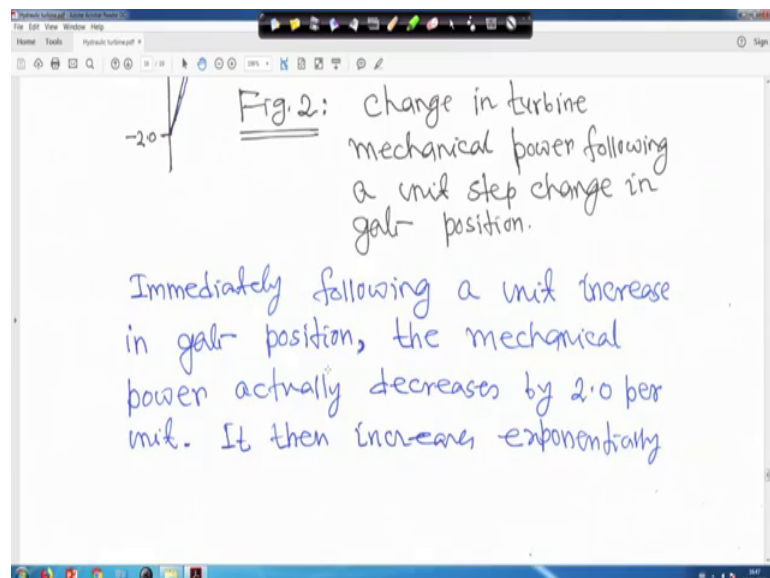

Now, figure 2 shows a plot of the response of an ideal turbine model with T_W is equal to 4 seconds. So, if you put here t is equal to 0, right at t is equal to 0 then basically it is becoming what? $1 - 3e^{-\frac{0}{4}}$, right. So, it is actually minus 2 here, right. And here if you make your t is equal to your what you call t tends to infinity then your this term will not be there, so it will become 1. So, actually it is settling to 1, right.

(Refer Slide Time: 09:59)

So, this is actually this plot is for T_H is equal to 4 second for a unit step input, right for a unit step input. So, that is why ΔG bar is attached here, right. So, if you look into that your what you call that change in turbine mechanical power following a unit step change in the gate position, right. So, this is actually no oscillation, actually going straight from this part to this point your what you call anything to the steady state in 8 to 10 second, that is a simple classical model small example.

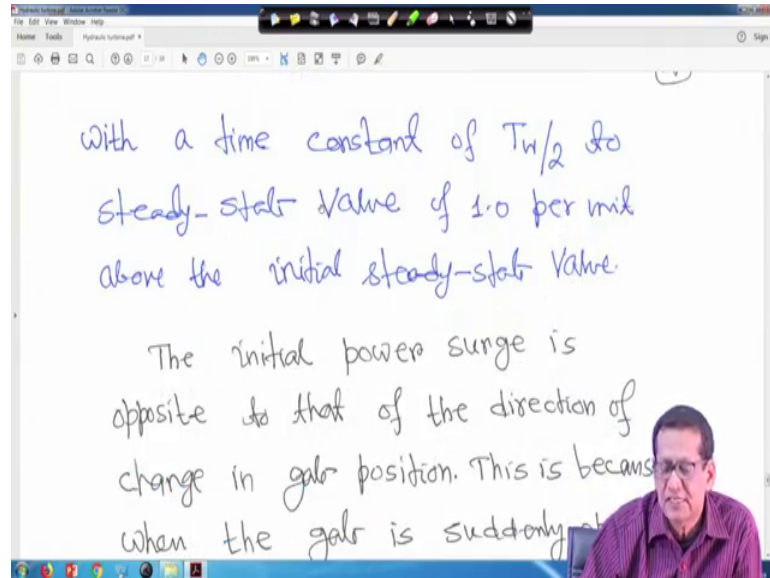

(Refer Slide Time: 10:37)

Immediately, following unit increase in gate position the mechanical power actually

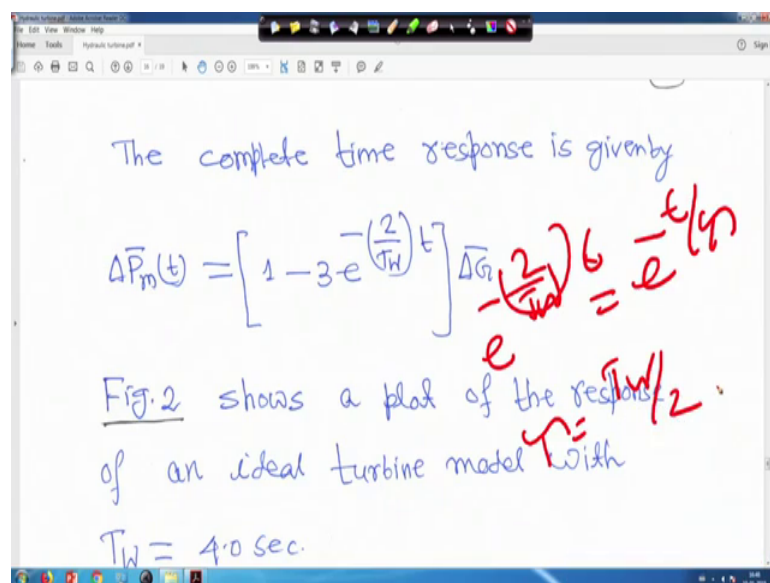

decreases by 2.0 per unit. It then increases exponentially with a time constant of T_W by 2, right.

(Refer Slide Time: 10:47)

Because here if you look into the expression it is e to the power minus 2 by T_W into t basically minus t by τ , so τ will be T_W actually τ will be T_W by 2 seconds. So, this part, this part you can write e to the power minus 2 sorry just hold on; e to the power minus 2 by $T_W t$, right.

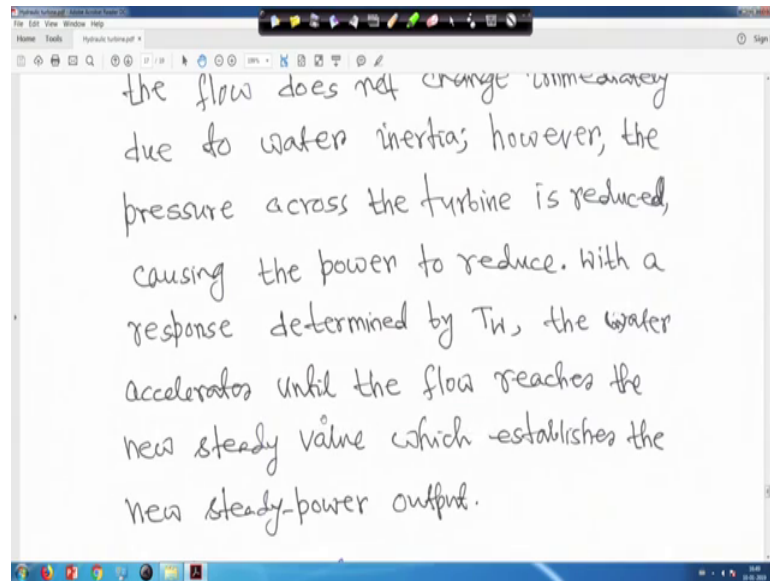

(Refer Slide Time: 11:11)

This equation can be written as e to the power minus t by τ . So, τ is the time

constant, right and τ is equal to actually $T W$ by 2, right. So, that means, if you draw a tangent like this. So, it will come here. So, at your what you call and this is $2 T W$ by 2 is equal to w is 4, so $T W$ is 4 4 by 2 is equal to this is the 2, right. Approximately I have made it here that is your 2, right. So, with a time constant to steady state value of 1.0 per unit above the initial steady state value.

(Refer Slide Time: 12:05)

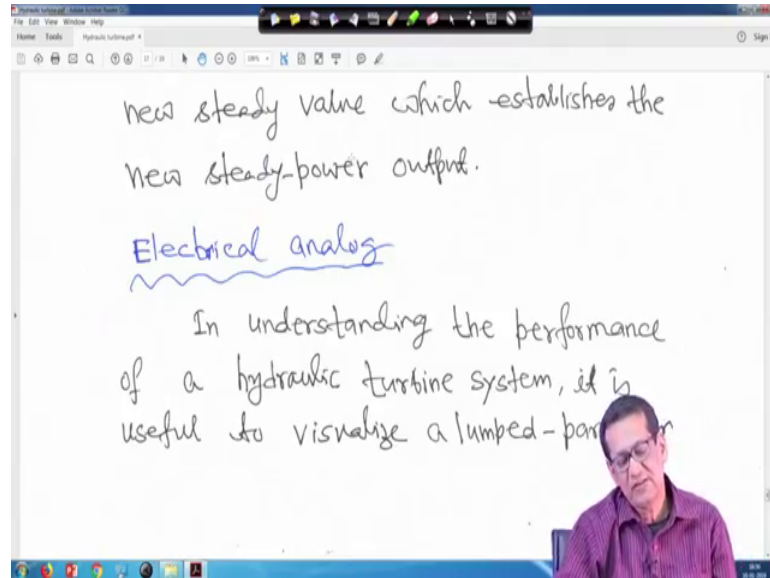

The initial power surge is opposite to that of the direction of the change in gate position, right. This is because when the gate is suddenly open the flow does not change immediately due to the water inertia, right. So, however, the pressure across the turbine is reduced, causing the power to reduce with the response determined by $T W$. The water accelerates until the flow reaches the new steady state value which establishes the new steady state power output.

So, for hydro turbine actually for hydro turbine that means, suppose there is a sudden increase in the load demand. So, initially what happened? That hydro power generation immediately that it cannot generate power instead of gauge in your what you call generating power initially decreases, after some time it goes up. So, that is why this is that your with this small your the turbine with this small example this is the thing.

Actually, for when we will connect to the system because governor thing will not consider, right initially actually if you plot the generation for hydro turbine initially it, I am just making like this initially it will be like this. And finally, it will settle something

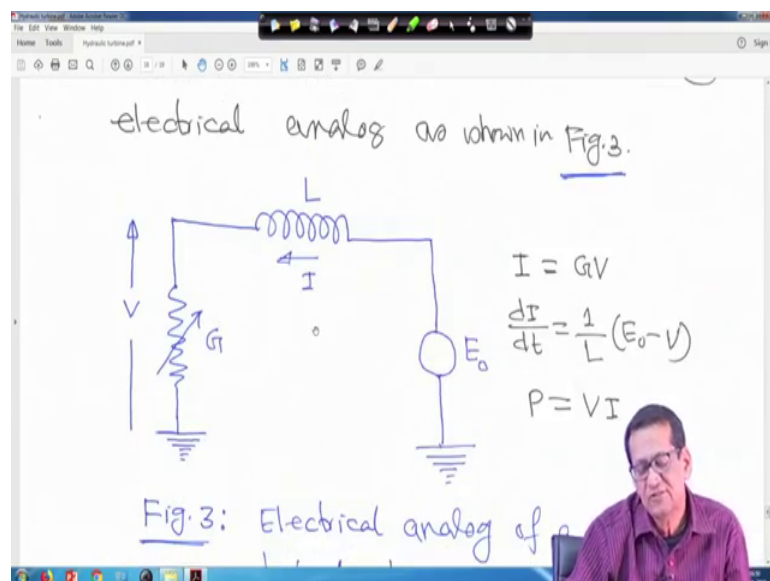

like this, right lot of oscillations will be there, but it is a simply first order model governors are not considered, but initially it will be like this, right.

(Refer Slide Time: 13:33)

So, therefore, next is the electrical analogy. Now, in understanding the performance of a hydraulic turbine system it is useful to visualise a lumped parameter electrical analogy as show in figure 3, right.

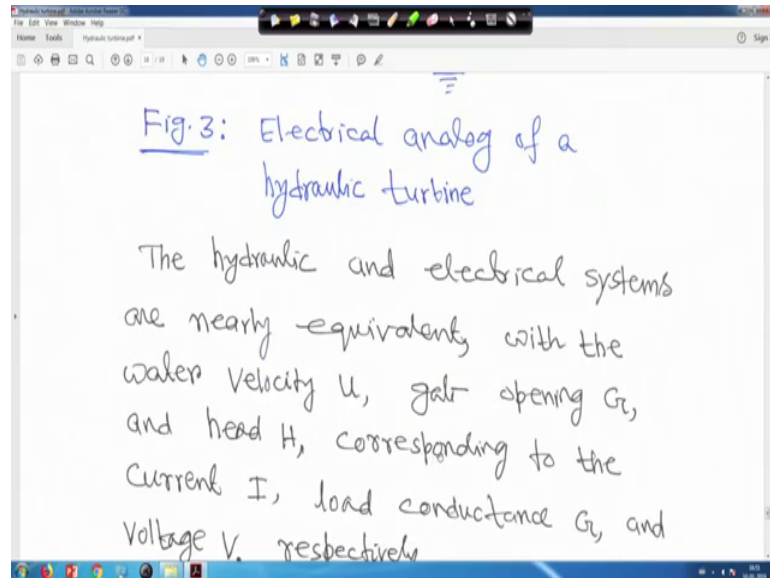

(Refer Slide Time: 13:45)

So, this is a your what you call a simple analogy, this is a variable conductance it is given G, an reciprocal of resistance, right and this voltage across be this is the current I and this

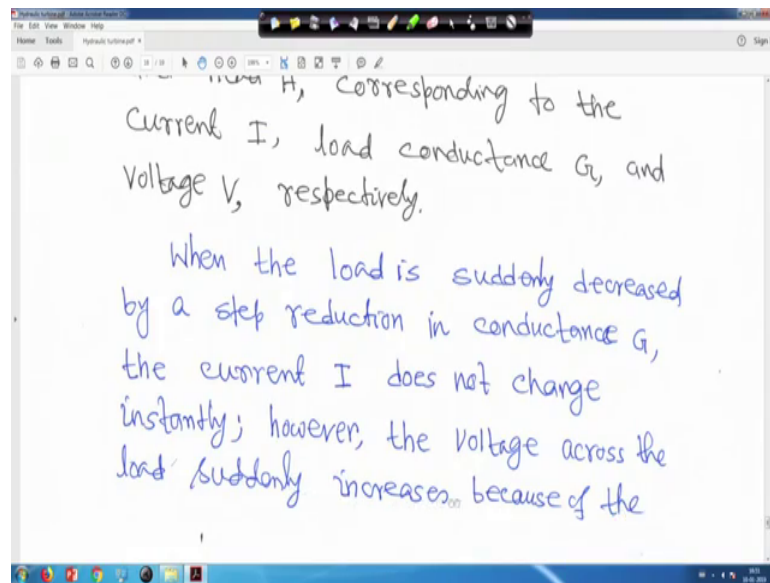

is inductor L and this is e_0 . I is equal to GV , dI by dt can be written as 1 upon L E_0 minus with this is E_0 and this is V . So, dI/dt is 1 upon L , actually $L dI/dt$ is equal to E_0 minus V and power P is equal to VI , right.

(Refer Slide Time: 14:19)

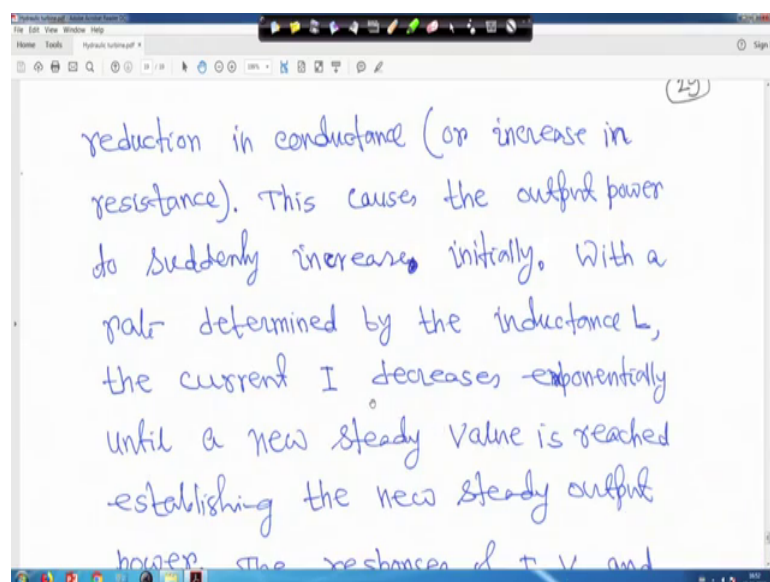

So, now, this is actually electrical analogy of a hydraulic turbines. So, how we will do this? The hydraulic and electrical system are nearly equivalent with the water velocity U gate opening G and head H , corresponding to the current I load conductance G an voltage V , right. So, there I mean they are analogues to each other; your what you call when you make this circuit, right.

(Refer Slide Time: 14:43)

So, when the load is suddenly decreased by step reduction in conductance G that your what you are doing is step reduction in conductance G means r is increasing, right that is current I does not change instantly, right. So, however, the voltage across the load suddenly increases because of the reduction in conductance or increase in the resistance, right.

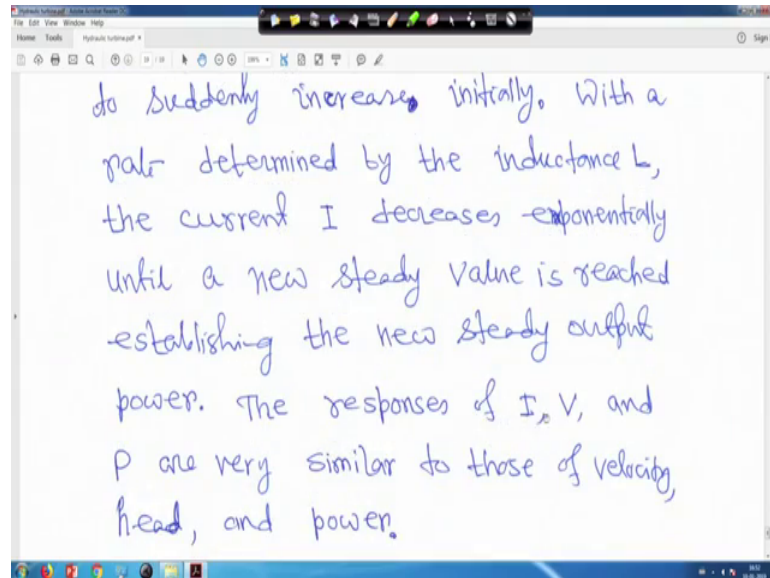

(Refer Slide Time: 15:05)

This causes the output power to suddenly increase. Initially so with a, so this causes the output power is suddenly initially actually this causes the output power to suddenly

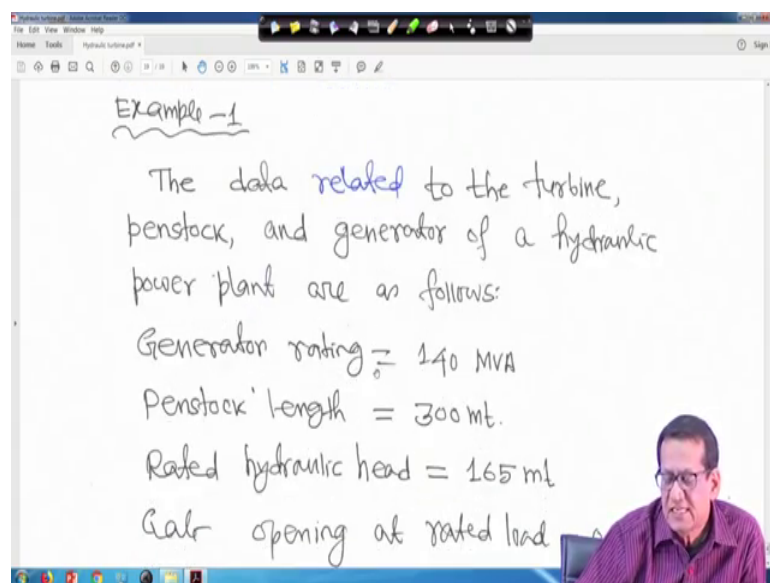

increase, right. With a rate determined by the inductance L the current I , decreases exponentially until a new steady value is reached establishing the new steady state output power, right.

(Refer Slide Time: 15:37)

The responses of I , V and P are very similar to those of velocity, head and power, right. So, this is actually your what you call that analogy that with that hydro turbine then this circuit is a analogy to that one, right.

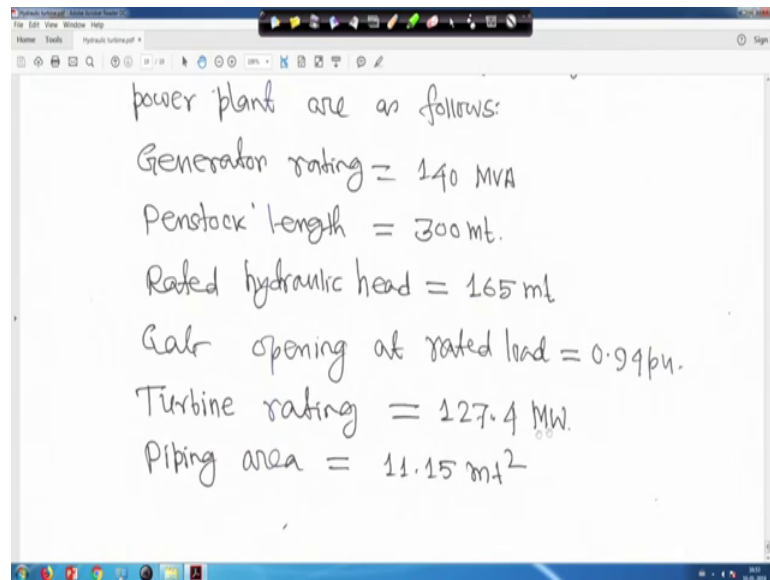

(Refer Slide Time: 15:59)

So, next is that example 1. So, the data related to the turbine penstock and generator of a

hydraulic power plant are as follows. Generator rating is given 140 MVA, penstock length is 300 meter, say rated hydraulic head 165 meter and gate opening at rated load is 0.94 per unit.

(Refer Slide Time: 16:19)

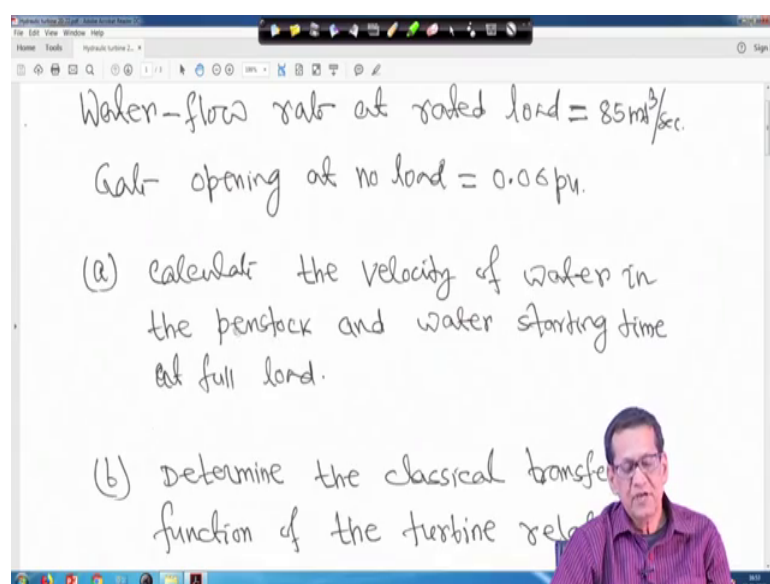

power plant are as follows:

- Generator rating = 140 MVA
- Penstock length = 300 mt.
- Rated hydraulic head = 165 mt.
- Gate opening at rated load = 0.94 pu.
- Turbine rating = 127.4 MW.
- Piping area = 11.15 m^2

So, turbine rating is 127.4 megawatt and piping area 11.15 meter square. These are the data given, right these are the data given. So, hold on we will go to the next phase. So, these are the data, right.

(Refer Slide Time: 16:43)

Water-flow rate at rated load = $85 \text{ m}^3/\text{sec}$.

Gate opening at no load = 0.06 pu.

(a) Calculate the velocity of water in the penstock and water starting time at full load.

(b) Determine the classical transfer function of the turbine related to the gate opening.

(A video inset of a man in a purple shirt is visible in the bottom right corner of the slide.)

So, water flow rate at rated load is 85 meter cube per second this is also given. Gate

opening at no load is equal to 0.06 per unit, right. So, you have to calculate the velocity of water in the penstock and water starting time at full load.

(Refer Slide Time: 17:05)

(b) Determine the classical transfer function of the turbine relating the change in power output to change in gate position at rated load.

Solution

(a) velocity of water in the penstock at rated load is

Next is determine the classical transfer function of the turbine relating to the change in power output to change in gate position at rated load. So, these two things we have to find out.

(Refer Slide Time: 17:17)

(a) velocity of water in the penstock at rated load is

$$U_r = \frac{\text{flow rate at rated load}}{\text{piping area}}$$

$$= \frac{85 \text{ m}^3/\text{sec}}{11.15 \text{ m}^2} = 7.62 \text{ m/sec.}$$

Water starting time T_w at full load,

$$T_w = \frac{L U_r}{g H_r} = \frac{300 \times 7.62}{9.81 \times 165} = 1.41 \text{ sec.}$$

Now, solution; the velocity of water in the penstock at rated load is that is your U_r is equal to flow rate at rated load divided by piping area. So, flow rate is given 85 meter

cube per second and piping area is 11.15 so, 85 by 11.15 meter per second. So, that is 7.62 meter per second, right. So, water starting time T W at full load; that we know this formula T W is equal to L U r divided by a g into H r, right. So, here it is given L is given 300 meter, U r is we have got 7.62 and this is a g is acceleration due to gravity 9.8 meter per second square and H r is 165, right. So, it is actually T W is 1.41 second, right that is the water starting time.

(Refer Slide Time: 18:13)

The classical transfer function of the turbine at rated load is

$$\frac{\Delta P_m (pu)}{\Delta G_r (pu)} = \frac{(1 - ST_W)}{(1 + 0.5 ST_W)}$$

$$= \frac{(1 - 1.41s)}{(1 + 0.705s)}$$

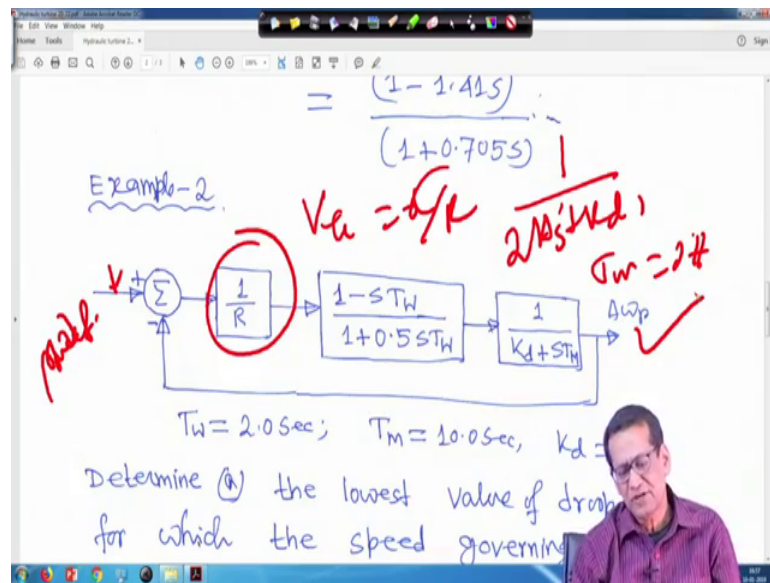

Example-2

$$= -\frac{1.41}{0.705} = -2$$

Now, the classical transfer function of the turbine at rated load is, we know this 1 minus S T W upon 1 plus 0.5 S T W, right. So, you put T W is 1.41 second and your both the numerator and denominator then transfer function will be 1 minus 1.41 S upon 1 plus 0.705 s, right.

So, in this case; in this case if you try to find out for a step input what will be the your what you call, that your value of initial value of delta P m 0. I mean what will be for this case at delta P m 0 will be that limit your what you call S tends to your infinity, that is t tends to 0. So, S S will be cancelled, we have seen before only this term will be left out. So, you divide numerator and denominator what you call by S, right if you divide numerator and denominator by S. So, it will be minus 1.41 divided by 0.705, so same as before minus 2, right. So, similarly your what you call the final value theorem also when t tends to infinity S tends to 0 it is 1, right.

(Refer Slide Time: 19:29)

Now, example 2; so, this example actually it is a simplest example. So, question is that here actually this hydro governor only we have represented by 1 upon R, that is k_g is equal to actually 1 upon R. But hydro governor modelling actually it is a second order governor model, right or sometimes it is API data governor model, right. So, electric hydraulic governor is there as well as mechanical hydraulic governor is also there. But there, mechanism is different, but ultimately overall transfer function will remain more or less same, right.

So, but those governor model we have not considered here. What we have done is we have simply represented some gain is equal to 1 upon R. So, here governor is not there. It will be your what you call a second your what you call it will be second order model. So, we do not want to complicate this. We have taken a simplest one, right and this is your reference speed reference, I have forgot to note it that this is actually speed reference, right.

And in the during the synchronous machine modelling we have seen that this model we are writing 1 upon $K_d + sT_m$, right. So, there also we have seen that 1 upon $2Hs + K_d$, right. So, here also; that means, your T_m actually if it is 2H, right it is 2H S. So, T_m is equal to 2H, but here T_m value is given, right. So, this way we have taken and that is why this is $\Delta\omega/R$. But if you take in AGC form also I will write you for you, right. So, this I have taken.

Now, following parameters your what you call that following parameters are taken T_w is equal to 2 second T_m is equal to your 10 second, right that means, H is equal to 5 because T_m is equal to 2 H and K_d we have considered as a 0, right. We have, taken your easy analysis we have taken K_d is equal to 0. Therefore, you have to determine the lowest value of droop R , this is that droop characteristic that governor, but other part transfer function that is a quadratic one we did not consider here, right.

So, just taken a simplest one; if you consider the quadratic one it will be very lengthy and complicated as well as classroom exercise is concerned, right for which the speed governing is stable.

(Refer Slide Time: 21:57)

$T_w = 2.0 \text{ sec}; T_m = 10.0 \text{ sec}, K_d = 0.$

Determine (a) the lowest value of droop R for which the speed governing is stable, and (b) the value of R for which the speed control action is critically damped.

Soln.

The characteristic equation (of the form $1 + GH = 0$) of the closed-loop system

And b, the value of R for which the speed control action is critically damped. So, you have to find out the lowest value of droop R for which the speed governing is stable. And second here is the value of R for which the speed control action is critically damped, right. So, this is my block diagram transfer function.

(Refer Slide Time: 22:21)

Which the speed control action is critically damped.

Soln.

The characteristic equation (of the form $1 + GH = 0$) of the closed-loop system is

$$1 + \frac{(1-2s)}{(2+s)} \times \frac{1}{10s} \times \frac{1}{R} = 0$$

Now, the characteristic equation of the form 1 plus GH is equal to 0 of the closed loop system is 1 plus your 1 minus 2 S upon 1 plus S into 1 upon 10 S into 1 upon R is equal to 0, right. So, if you make 1 plus GH, right. So, here your what you call you put T W is equal to 2, right. So, it is actually 1 minus because T W is 21 minus 2 S divided by it T W 2, so 1 plus S. So, that is why this is your 1 minus 2 S upon 1 plus S, right here.

Now, next is K d is 0, but T m is 10, that is 1 upon 10 S, right. So, that is why it is 1 upon 10 S into this 1 upon R, here it is 1 upon R into 1 upon R is equal to 0, right. So, this is the characteristic equation of the closed loop system.

(Refer Slide Time: 23:19)

(22)

$$\therefore 10RS^2 + (10R-2)S + 1 = 0$$

(a) For stability, the roots of the characteristic equation have to be in the left side of the complex s-plane. In case of a quadratic a sufficient and necessary condition is that all quadratic coefficients

Now, if you simplify this one, if you simplify this one the $10R S^2$ plus $10R$ minus 2 into S plus 1 is equal to 0 . So, this is the simple quadratic equation, right. Now, for stability the roots of the characteristic equation have to be in the left side of the complex S plane. That means, whatever roots we will get that they will lie on the left top of the S plane that is real part is negative, right.

(Refer Slide Time: 23:43)

$$\therefore 10RS^2 + (10R-2)S + 1 = 0$$

(a) For stability, the roots of the characteristic equation have to be in the left side of the complex s-plane. In case of a quadratic, a sufficient and necessary condition is that all quadratic coefficients are positive. Hence,

$10R > 0$

In case of a quadratic a sufficient and necessary condition is that all quadratic coefficients are positive, right I mean all the coefficient will be positive that is your $10R$

greater than 0 is a first thing, sorry. So, $10R$ greater than 0, that is R greater than 0, right. Similarly, this coefficient $10R$ minus 2 this also has to be greater than 0.

(Refer Slide Time: 24:07)

is that all quadratic coefficients are positive. Hence,

$$10R > 0, \text{ i.e., } R > 0$$

and

$$10R - 2 > 0, \text{ i.e., } R > 0.20$$

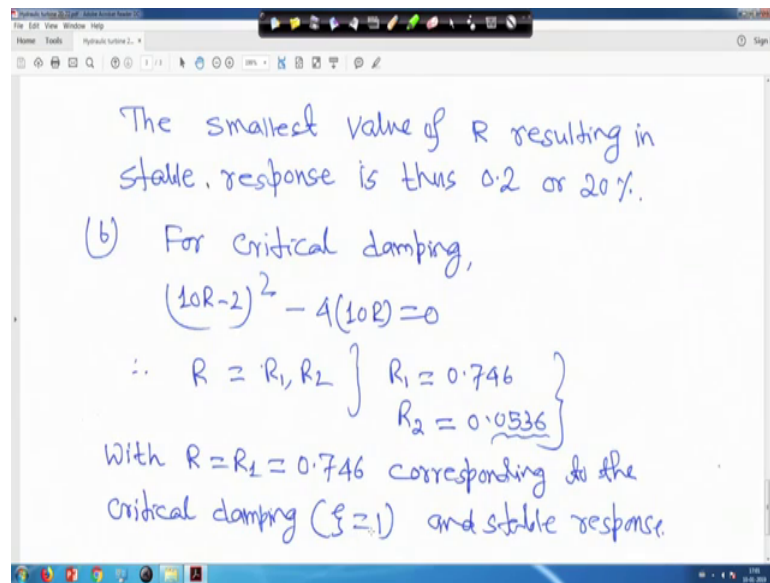

The smallest value of R resulting in stable response is thus 0.2 or 20%.

(b) For critical damping,

$$(10R - 2)^2 = 0$$

Therefore $10R$ minus 2 greater than 0 that is R greater than 0.2 because $10R$ greater than 2, so, R greater than 2 by 10. So, R greater than 0.2, right, the smallest value of r resulting in stable response is that 0.2 or 20 percent, right this is the smallest value of R . Now, for critically damped, if you want then if you want critically damped then your what you call roots will be same, right roots will be same that mean b square minus $4ac$ will be greater than will be is equal to 0.

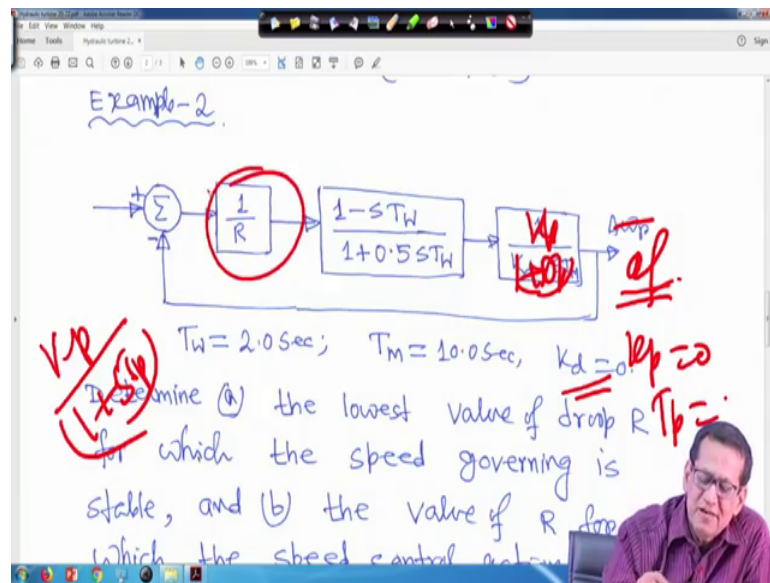

(Refer Slide Time: 24:43)

So, second case or critical damping that b this is b 10 R minus whole square minus 4 into a, this is a and c is 1. So, minus 4 into 10 R is equal to 0, right. If you solve for this one you will get R 1 is equal to 0.746 and R 2 is equal to 0.0536. But when R is equal to 0.746 corresponding to a critical damping that is your damping ratio zeta is equal to 1, right and it gives a stable response, right. But if you consider R 2 is equal to this one, R 2 is equal to this one this will be your unstable response, right. So, this that means, your this is the correct answer, but this is not, right. You can verify; you can verify even is mat level, so, you can verify.

So, this one for hydro turbine this way we have taken, but let me tell you one thing regarding this modelling that suppose this problem this problem it is taken your what you call your 1 upon K d plus S T m. Now, it is an isolated system not connected this thing.

(Refer Slide Time: 25:53)

But when we representing AGC we are representing K_p upon $1 + sT_p$ this from, right therefore, this equation instead of this law we can make it also this law K_p upon $1 + sT_p$, but at that time this will be your Δf , right. Suppose, if you make it like this and this will be your Δf . So, in that case if you what you call if you make a K_p upon $1 + sT_p$ at that time your K_p has to be known and T_p has to be known, right both has to be given. But in this case what do we do, that K_d that is your when you are doing that your AGC thing that ΔP upon Δf that is your actually d the damping, right that your use that is you are d term we are using, right.

But otherwise if you what you call if you take K_p upon $1 + sT_p$ absolutely no problem, but at the time it will be Δf . So, results and other thing whatever we will get the philosophy will remain same, right. Only thing is that this part here that hydro governor modelling actually it will makes them complicated then your steam turbine that your and this one actually makes our classroom exercise will make things difficult, right.

So, whenever some general idea is that for thermal power plant while for your AGC modelling we have seen that it has generation rate constant, right. So, generally it varies from unit to unit steam turbine to steam turbine, but generally it is 3 percent to 10 percent per minute with that it lies. Whereas, for hydro turbine actually the generation rate limit and in the case of steam turbine the increase or decrease the generation rate increasing or decreasing it is more or less same.

Whereas, in the case of hydro turbine it is not like that, right. So, and it is very high value, right. Some typical thing is that that 360 your person per minute for rising the generation and for lowering the generation it is 270 person per minute. So, it is so high that your generation rate GRC or Generation Rate Constant for hydro turbine it does not have any effect on the your what you call dynamic responses. But because of that governor time constant hydro turbine, right it is it has a your different time constant and larger than your steam turbine governor time your what you call time constant.

That is why responses when you will take I mean for the your what you call that your theoretical exercise or your for academic interest if you take those transfer function of the governor and see the responses it takes more time to settle because it is because it is because of its time constant, right. It takes more time to settle compared to your steam turbine.

But when you use interconnected one area say thermal system another area is hydro system there also because of this effect you will find it takes longer time to settle, right. So, this is some general ideas, so, hydro turbine. So, after this we have one more hour. So, there we will see different type of limiters and some new things, right.

So, with this thank you very much. We will back again.
