

**Numerical Methods**  
**By Dr. Sanjeev Kumar**  
**Department of Mathematics**  
**Indian Institute of Technology Roorkee**  
**Lecture 38**  
**Numerical Methods - 2**

Hello friends. So welcome to the third lecture of this module and in this lecture we will continue from the last lecture in which we have introduced Euler's method and in the Euler's method we have seen that we need to reduce the step size for getting a better accuracy and hence reducing the step size means you need to do more calculations. So in this lecture our aim is to develop a whole family of numerical methods that can attain any order of accuracy. Unlike the Euler's method where we are having an accuracy of order each.

(Refer Slide Time: 1:03)

The slide is titled "Taylor's series method" in a blue header. The main content area is light gray and contains two bullet points in a light blue box. The first bullet point states: "After Euler's method, our next aim is to develop a whole family of numerical methods that can attain any order of accuracy, namely the Taylor methods." The second bullet point states: "For these methods however, we need to know how to determine higher order derivatives of the solution of a differential equation at a point, and this is one of the topics of this lecture." The footer of the slide is dark blue and contains the IIT Roorkee logo, the NPTEL Online Certification Course logo, and the number 2.

So here we will do that Euler's method in this lecture and specifically I will talk about quadratic Taylor method and then I will tell you how we can generalize Taylor method up to any order of any order. But in Taylor's method we need to know how to determine higher order derivatives of the solution of a differential equation at a point and this is also we will explore in this lecture that how to calculate higher order derivative for a given function. So let us start with quadratic Taylor method.

(Refer Slide Time: 1:41)

The quadratic Taylor method is based on the more accurate approximation

$$f(x_0 + h) = f(x_0) + hf'(x_0) + \frac{h^2}{2}f''(x_0)$$

To describe the algorithm, we need to specify how the numerical solution can be advanced from a point  $(x_k, y_k)$  to a new point  $(x_{k+1}, y_{k+1})$  with  $x_{k+1} = x_k + h$ . The basic idea is to use the above equation and compute  $y_{k+1}$  as

$$y_{k+1} = y_k + hy'_k + \frac{h^2}{2}y''_k$$

IT ROORKEE NPTEL ONLINE CERTIFICATION COURSE 3

So the quadratic Taylor method approximation is based on the more accurate approximation that is the approximation of second order derivative like in Euler's method we have taken only upto first order derivative but here we are taking up to second order derivative so a function can be approximated about a point  $x_0$  by this expression that is  $f(x_0 + h) = f(x_0) + hf'(x_0) + \frac{h^2}{2}f''(x_0)$ .

To describe the algorithm we need to specify how the numerical solution can be advanced from a point  $(x_k, y_k)$  to a new point  $(x_{k+1}, y_{k+1})$ . Where  $x_{k+1} = x_k + h$ . Now basic idea is to use the above equation and compute  $y_{k+1}$  so by the Taylor series expansion we can write  $y_{k+1} = y_k + hy'_k + \frac{h^2}{2}y''_k$ .

So in this expression you can see we are having  $y'_k$  and  $y''_k$ . So  $y'_k$  can be given by the differential equation from our initial value problem. However we need to calculate  $y''_k$  here. So for calculating  $y''_k$  we will use the lemma.

(Refer Slide Time: 3:03)

The quadratic Taylor method

The numbers  $y_k$ ,  $y'_k$  and  $y''_k$  are approximations to the function value and derivatives of the solution at  $x$  and can be obtained as:

**Lemma:** Let  $y' = f(x, y)$  be a differential equation with initial condition  $y(x_0) = y_0$ , and suppose that the derivatives of  $f(y, x)$  of order  $p - 1$  exist at the point  $(x_0, y_0)$ . Then the  $p^{\text{th}}$  order derivative of the solution  $y(x)$  at  $x = x_0$  can be expressed as,

$$y^{(p)}(x_0) = F_p(x_0, y_0)$$

where,  $F_p$  is a function defined by  $f$  and its derivatives of order less than  $p$ .

 IIT ROORKEE
  NPTEL ONLINE CERTIFICATION COURSE
 4

And in this lemma we are having a its function  $Y$  prime that is equal to  $F$  of  $XY$  that is the given differential equation with initial condition  $Y X$  nought equals to  $Y$  nought. In the same time suppose that the derivative of  $F$  of order  $P$  minus 1 exists at the point  $X$  nought,  $Y$  nought then the  $P$ th order derivative of the solution  $Y X$  at  $X$  equal to  $X$  nought can be expressed in terms of  $F_P$  capital  $F_P X$  nought  $Y$  nought.

Where capital  $F_P$  is a function defined by  $F$  and its derivative of order less than  $P$ . So let us take an example to get a better understanding of this lemma.

(Refer Slide Time: 3:47)

The quadratic Taylor method

**Example**

Let

$$y' = F_1(x, y) = x + y^2; \quad \text{and} \quad y(x_0) = y_0$$

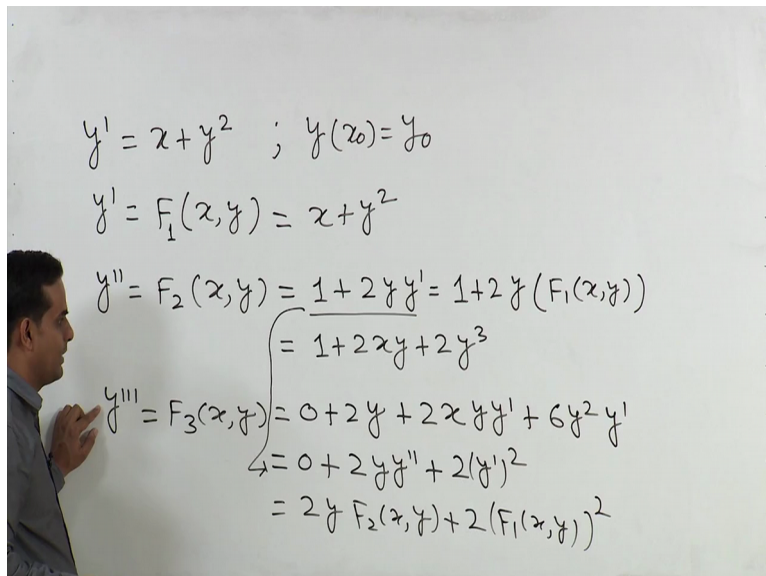

Then,

$$y'' = F_2(x, y) = 1 + 2yy' = 1 + 2y(x + y^2) = 1 + 2xy + 2y^3,$$

$$y''' = F_3(x, y) = 2((x + y^2)^2 + y(1 + 2xy + 2y^3))$$

This shows the explicit expressions for  $F_1$ ,  $F_2$  and  $F_3$ .

 IIT ROORKEE
  NPTEL ONLINE CERTIFICATION COURSE
 5

So in this example we are having a differential equation  $Y'$  equals to  $X$  plus  $Y$  square together with initial condition  $Y$  of  $X$  nought equals to  $Y$  nought. Now let us assume that  $Y'$  equals to  $F$  of  $XY$  or I will write  $F_1$  of  $XY$ . Now if I calculate  $Y$  double prime that is some according to previous lemma I am having  $F_2$  of  $XY$ . And this is the differentiation of this particular term with respect to  $X$ .

So it will be 1 for this particular  $X$  and then 2  $Y$  into  $Y'$  so that is 1 plus 2 times  $Y$  and  $Y'$  prime is  $F_1$  of  $XY$ . So here you can note down for calculating the second order derivative of  $Y$  that is the  $Y$  double prime we need the value that is value of  $Y$  as well as value of capital  $F_1$   $XY$ . That is the derivative of  $Y$  which is less than order 2. And this is coming out now if I substitute the value of  $F_1$   $XY$  from here that is your  $X$  plus  $Y$  square.

So it will be 1 plus 2 XY plus 2 times Y cube. Similarly we can calculate higher order derivative for example if I want to calculate Y triple prime that will be F3 XY so it will become 0 plus 2 times Y plus twice XY into Y prime plus 6 Y square into Y prime. Or somewhere I can write if I want to calculate from here directly 0 plus 2 times Y into Y double prime.

So if I am coming from here so it will be 0 plus 2 times Y into Y double prime plus 2 Y prime whole square. So basically each two times Y into F2 XY plus 2 times F1 XY whole square. So here again you cannot (( ))(6:57). I am using the value of Y, I am using the capital F1, I am using capital F2 for calculating capital F3 according to previous lemma and by substituting all these values I can get Y triple prime. Now how to use quadratic Taylor method?

(Refer Slide Time: 7:18)

The quadratic Taylor method

Example

Let us consider the differential equation

$$y' = f(x, y) = F_1(x, y) = x - \frac{1}{1+y}; \quad y(0) = 1$$

which we want to solve on the interval  $[0, 1]$  with  $h = 0.5$  using a quadratic Taylor method.

Here,

$$y''(x) = F_2(x, y) = 1 + \frac{y'(x)}{(1+y)^2}$$

IT ROORKEE NPTEL ONLINE CERTIFICATION COURSE 6

For that again we will consider an example of an initial value problem that is given as Y prime equal to a small f of XY that is also my capital F1 of XY and it is given as X minus 1 over 1 plus Y and initial condition is Y at X equals to 0 equals to 1. If we want to solve these particular initial value problem on the interval 0 to 1 with step size h equals to 0 point 5 using quadratic Taylor method.

So first of all we need to calculate the second order derivative of Y for applying the quadratic Taylor method and for doing that Y double prime X can be given as F2 of XY that is basically 1 plus Y prime X upon 1 plus Y whole square. So now after that what I will do?

(Refer Slide Time: 8:21)

$$y' = x - \frac{1}{1+y}; \quad y(0) = 1 \quad [0, 1]; \quad h = 0.5$$

$$y'' = 1 + \frac{y'(x)}{(1+y)^2} \quad \left| \begin{array}{l} x_0 = 0; \quad x_1 = 0.5; \quad x_2 = 1 \\ y(x_0) = y_0 = 1 \quad y(x_1) = ? \quad y(x_2) = ? \end{array} \right.$$

$$y(0.5) = y_0 + h y'_0 + \frac{h^2}{2} y''_0 \quad \left| \begin{array}{l} y'_0 = y'_0 = -\frac{1}{2} \\ y''_0 = 1 - \frac{1}{8} = \frac{7}{8} \end{array} \right.$$

$$= 1 + (0.5)\left(-\frac{1}{2}\right) + \frac{(0.5)^2}{2} \left(\frac{7}{8}\right)$$

$$y(1) = y_1 + h y'_1 + \frac{h^2}{2} y''_1 = 0.859375$$

$$= 0.9641..$$

I need to solve a differential equation  $Y'$  equals to  $X$  minus  $1$  over  $1$  plus  $Y$ .  $Y$  at  $X$  equals to  $0$  is given as  $1$ . So I want to solve this on the interval  $0$  to  $1$  with  $h$  equals to  $0.5$ . So now  $Y''$  is  $1$  plus  $Y'$   $X$  over  $1$  plus  $Y$  whole square. So here  $X$  is  $0$ ,  $X_1$  is  $0.5$  that is  $0$  plus  $h$  and  $X_2$  is  $1$ . At initial  $Y$  at  $X_0$  that is my  $Y_0$  it is  $1$ . Now I need to calculate  $Y$  at  $0.5$  and  $Y$  at  $1$  using the quadratic Taylor method.

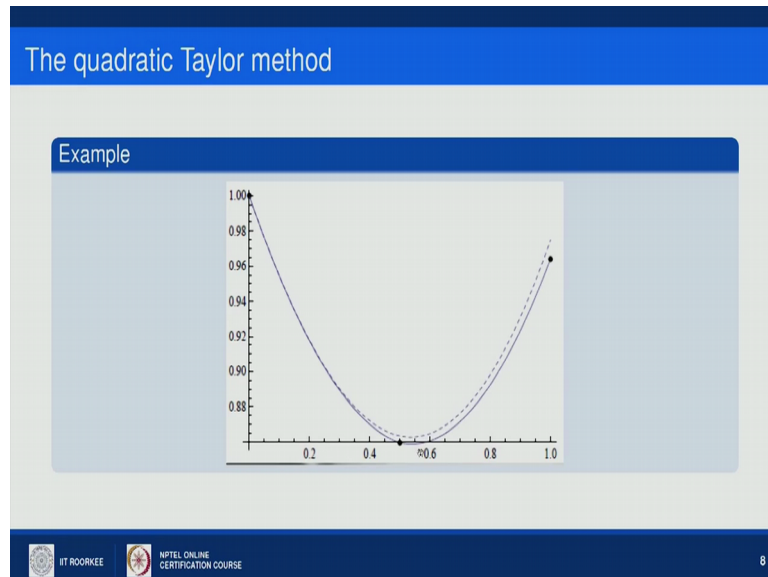

So for doing this what I want I will write that  $YX$  equals to  $Y_0$  plus  $h$  times  $Y'$   $0$  plus  $h^2$  over  $2$   $Y''$   $0$ . Now  $Y_0$  is given as  $1$ . If I want to calculate  $Y'$   $0$  that is  $Y'$   $0$ . so from here I will calculate  $Y'$   $0$   $X$  is  $0$ ,  $0$  minus  $1$  upon  $1$  plus  $1$  so it is minus  $0.5$ .  $Y''$   $0$  will I can calculate from here. So  $1$  plus  $Y'$   $0$  that is minus  $0.5$  upon  $1$  plus  $1$ .

So  $1 + 1$  will become two. A two square will become four. So  $1 - 1$  upon 8. It is basically  $7$  upon  $8$ . So after putting these values here  $Y_0$  is  $1 + H$  is  $0.5$   $Y'$   $0$  is minus  $1$  by  $2$  plus  $0$  point  $5$  whole square upon  $2$  and then  $Y''$   $0$  is  $7$  by  $8$  and after simplifying this I will get a value  $0$  point  $85937$ . So this is the approximation of  $Y$  at  $X$  equals to  $0$  point  $5$ .

Again if I want to calculate  $Y$  at  $1$  what I will use? I will use  $Y_1 + H$  time  $Y'$   $1$  plus  $H$  square upon  $2$   $Y''$   $1$ . So I am having value of  $Y_1$  which I will kept  $H$   $0$  point  $859375$ . I will calculate the value of  $Y'$   $1$  from this formula. After putting the value  $X$   $0$  point  $5$  and  $Y$  is this value and then similarly I can calculate  $Y''$  with the help of this expression.

And then finally I will get this value which is coming out something  $0$  point  $9641$  and so on. So this is the overall procedure for implementing quadratic Taylor method For solving initial value problem. And here we are getting more accuracy compare to the Euler's method without reducing the step size means taking the large steps.

(Refer Slide Time: 12:57)

So this is the curve of the approximate solution and the exact solution. Here you can see between  $0$  to  $1$  the curve the two curves are quite similar and hence we are getting a good approximation with larger step size using the quadratic Taylor method. If we talk about Taylor methods of higher order we can do it.

(Refer Slide Time: 13:22)

The quadratic Taylor method is easily generalized to higher degrees by including more terms in the Taylor polynomial. The Taylor method of degree  $p$  uses the formula

$$y_{k+1} = y_k + hy'(k) + \frac{h^2}{2} y''_k + \dots + \frac{h^{p-1}}{(p-1)!} y_k^{(p-1)} + \frac{h^p}{(p)!} y_k^{(p)}$$

to advance the solution from the point  $(x_k, y_k)$  to  $(x_{k+1}, y_{k+1})$ .  
Just like for the quadratic method, the main challenge is the determination of the derivatives, whose complexity may increase quickly with the degree. It is possible to make use of software for symbolic computation to produce the derivatives.

IT ROORKEE NPTEL ONLINE CERTIFICATION COURSE 10

The quadratic Taylor method is easily generalized to higher degrees by including more terms in the Taylor polynomial. For example that Taylor method of degree  $p$  uses the formula  $y$  at  $x_{k+1}$  equals to  $y_k$  plus  $h$  times  $y'$  at  $x_k$  plus  $\frac{h^2}{2}$   $y''$  at  $x_k$  and upto  $p$ th order derivative. That is the last term will be a  $h^p$  divided by factorial  $p$  into  $y_k^{(p)}$ .

To advance the solution from the point  $(x_k, y_k)$  to point  $(x_{k+1}, y_{k+1})$  we will use this formula. So just like for the quadratic method the main challenge is to determination of the derivatives. How to determine higher order derivatives? And for that we can use the same lemma however we have to do a lot of computations and hence the complexity increase quickly with the degree.

It is possible to make use of software for symbolic computation to produce the derivatives of higher degree. Now if we talked about error in quadratic Taylor method so we can drive it in this way. So  $y$  at  $x_{k+1}$  can be given by  $y$  at  $x_k$  plus  $h$  times  $y'$  at  $x_k$  plus  $\frac{h^2}{2}$   $y''$  at  $x_k$  plus third and higher order derivatives.

(Refer Slide Time: 14:51)

Taylor's series method

Error analysis

Consider the Taylor's series

$$y(x_n + h) = y(x_n) + hy'(x_n) + \frac{h^2}{2}y''(x_n) + \mathcal{O}(h^3) \quad (1)$$

In (1), we will substitute  $y' = f(x, y(x))$  and  $y''(x) = f_1(x, y) := \frac{d}{dx}f(x, y(x))$  and so on

This gives

$$y_{n+1} = y_n + hy'_n + \frac{h^2}{2}y''_n, y_0 = Y \quad (2)$$

where  $y'_n := f(x_n, y_n)$  and  $y''_n = f_1(x_n, y_n)$ .

11

So in this equation we will substitute  $Y$  prime is  $F$  of  $X$   $Y$  and  $Y$  double prime is  $F_1$  of  $X$   $Y$  that is the derivative of  $F$  with respect to  $X$  and so on. So this gives  $Y_{n+1}$  equals to  $Y_n$  plus  $H$  times  $Y$  prime  $n$  plus  $H$  square upon  $2$   $Y$  double prime  $n$  with initial condition  $Y_0$  equals to capital  $Y$ . Here  $Y$  double prime  $n$  as you know is  $F$  at  $X_n$   $Y_n$  and  $Y$  double prime  $n$  is  $F_1$   $X_n$   $Y_n$ .

(Refer Slide Time: 15:31)

Taylor's series method

Error analysis

Consider the Taylor's series

$$y(x_n + h) = y(x_n) + hy'(x_n) + \frac{h^2}{2}y''(x_n) + \mathcal{O}(h^3) \quad (1)$$

In (1), we will substitute  $y' = f(x, y(x))$  and  $y''(x) = f_1(x, y) := \frac{d}{dx}f(x, y(x))$  and so on

This gives

$$y_{n+1} = y_n + hy'_n + \frac{h^2}{2}y''_n, y_0 = Y \quad (2)$$

where  $y'_n := f(x_n, y_n)$  and  $y''_n = f_1(x_n, y_n)$ .

11

So taking the difference between 1 and 2 we get the in the left hand side it will be  $Y_{n+1}$  minus  $Y$  at  $X_n$  plus  $H$ . So that will be the error in  $n$  plus 1 iteration.

(Refer Slide Time: 15:39)

Taylor's series method

Error analysis

Taking difference between equations (1) and (2), we get

$$e_{n+1} = e_n + h(f(x_n, y(x_n)) - f(x_n, y_n)) + \frac{h^2}{2}(f_1(x_n, y(x_n)) - f_1(x_n, y_n)) + \mathcal{O}(h^3)$$

Assuming both  $f$  and  $f_1$  are Lipschitz, we have

$$|e_{n+1}| \leq |e_n| + hk|y(x_n) - y_n| + \frac{1}{2}h^2k_1|y(x_n) - y_n| + \mathcal{O}(h^3)$$

$$\leq |e_n|(1 + hk + \frac{1}{2}h^2k_1) + ch^3$$

 IIT ROORKEE
  NPTEL ONLINE CERTIFICATION COURSE
 12

And let us denote it E of N plus 1 equals to if you take the

(Refer Slide Time: 15:46)

Taylor's series method

Error analysis

Consider the Taylor's series

$$y(x_n + h) = y(x_n) + hy'(x_n) + \frac{h^2}{2}y''(x_n) + \mathcal{O}(h^3) \quad (1)$$

In (1), we will substitute  $y' = f(x, y(x))$  and  $y''(x) = f_1(x, y) := \frac{d}{dx}f(x, y(x))$  and so on

This gives

$$y_{n+1} = y_n + hy'_n + \frac{h^2}{2}y''_n, y_0 = Y \quad (2)$$

where  $y'_n := f(x_n, y_n)$  and  $y''_n = f_1(x_n, y_n)$ .

 IIT ROORKEE
  NPTEL ONLINE CERTIFICATION COURSE
 11

See the first time in right hand side it will be YN minus YXN.

(Refer Slide Time: 15:53)

Taylor's series method

Error analysis

Taking difference between equations (1) and (2), we get

$$e_{n+1} = e_n + h(f(x_n, y(x_n)) - f(x_n, y_n)) + \frac{h^2}{2}(f_1(x_n, y(x_n)) - f_1(x_n, y_n)) + \mathcal{O}(h^3)$$

Assuming both  $f$  and  $f_1$  are Lipschitz, we have

$$|e_{n+1}| \leq |e_n| + hk|y(x_n) - y_n| + \frac{1}{2}h^2k_1|y(x_n) - y_n| + \mathcal{O}(h^3)$$
$$\leq |e_n|(1 + hk + \frac{1}{2}h^2k_1) + ch^3$$

12

So this I am writing  $e_n$  plus  $h$  times  $f$  at  $x_n, y(x_n)$  minus  $f$  at  $x_n, y_n$  plus second order term and then third and high order terms. If we assume that both  $f$  as well as  $f_1$  are Lipschitz continuous then we can replace these two expressions in round brackets like this one and this one by the definition of Lipschitz continuity in this way that  $e_{n+1}$  will be less than equal to  $e_n$  plus  $h$  times  $k|y(x_n) - y_n|$ .

So  $k$  is Lipschitz constant for this particular expression plus  $\frac{1}{2}h^2k_1$  and again this term. That is basically  $e_n$ . It is again  $e_n$ . So this after simplification I can write  $e_n$  if I take out 1 from here plus  $hk$  from here plus half times  $h^2k_1$  plus third and higher order terms. This expression can be written in this form.

(Refer Slide Time: 17:00)

The slide is titled "Taylor's series method" and contains a section for "Error analysis". It shows three mathematical expressions for the error, followed by a concluding statement. The footer includes logos for IIT ROORKEE and NPTEL ONLINE CERTIFICATION COURSE, and the slide number 13.

Taylor's series method

Error analysis

$$\leq \alpha^n |\epsilon_0| + ch^3(1 + \alpha + \alpha^2 + \dots + \alpha^{n-1})$$
$$\leq \alpha^n |\epsilon_0| + ch^2 \frac{(\alpha^n - 1)}{\alpha - 1}$$
$$\approx e^{kx} \left( |\epsilon_0| + \frac{ch^2}{k} \right)$$

The error is guaranteed to be of order  $h^2$  which is an immense improvement over Euler's method.

IIT ROORKEE NPTEL ONLINE CERTIFICATION COURSE 13

If I used the expression for the error from the first iteration that is  $E$  nought that is the initial error and finally this sum can be written in this way that is 1 plus alpha plus alpha square plus upto alpha  $N$  minus 1. In this particular form and finally it is coming out in this way. So this particular expression gives a guarantee to be that the error will be of order  $H$  square which is an immense improvement over Euler's method where we were having the accuracy of order  $H$ .

(Refer Slide Time: 17:35)

The slide is titled "Taylor's series method" and contains an "Example" and a "Solution" section. The example asks for the Taylor series of  $f(x) = \cos x$  about  $x = 0$ . The solution shows the general Taylor series formula and then applies it to the cosine function. The footer includes logos for IIT ROORKEE and NPTEL ONLINE CERTIFICATION COURSE, and the slide number 14.

Taylor's series method

Example

Determine the Taylor series for the function  $f(x) = \cos x$  about  $x = 0$ .

Solution

From Taylor's series, we have

$$\cos x = \sum_{n=0}^{\infty} \frac{f^{(n)}(0)}{n!} x^n$$
$$= \frac{f^{(0)}(0)}{0!} + \frac{f^{(1)}(0)}{1!} x + \frac{f^{(2)}(0)}{2!} x^2 + \frac{f^{(3)}(0)}{3!} x^3 + \dots$$

IIT ROORKEE NPTEL ONLINE CERTIFICATION COURSE 14

We can also use this Taylor's series for finding the approximation of a function about a given point for example if I want to find out the expression of  $f(x) = 2 \cos x$  about  $x = 0$

to 0. So Taylor's series is given by this 1 and hence we I am having different order derivatives in different terms after calculating all these at x equals to 0, so I will get 1, 0, minus 1, 0, 1.

(Refer Slide Time: 18:05)

Taylor's series method

Example cont...

We have  $f(x) = \cos x$ .

$$f^{(0)}(x) = \cos x, \quad f^{(0)}(0) = 1$$

$$f^{(1)}(x) = -\sin x, \quad f^{(1)}(0) = 0$$

$$f^{(2)}(x) = -\cos x, \quad f^{(2)}(0) = -1$$

$$f^{(3)}(x) = \sin x, \quad f^{(3)}(0) = 0$$

$$f^{(4)}(x) = \cos x, \quad f^{(4)}(0) = 1$$

...

15

Taylor's series method

Example cont...

Using all these values in Taylor's series formula, we get

$$\cos x = \frac{1}{0!} + 0 - \frac{x^2}{2!} + 0 + \frac{x^4}{4!} + 0 - \frac{x^6}{6!} + 0 + \frac{x^8}{8!} + \dots$$

Here, every other term is zero. So, we can rewrite above series as

$$\cos x = \frac{1}{0!} - \frac{x^2}{2!} + \frac{x^4}{4!} - \frac{x^6}{6!} + \frac{x^8}{8!} + \dots$$

Or

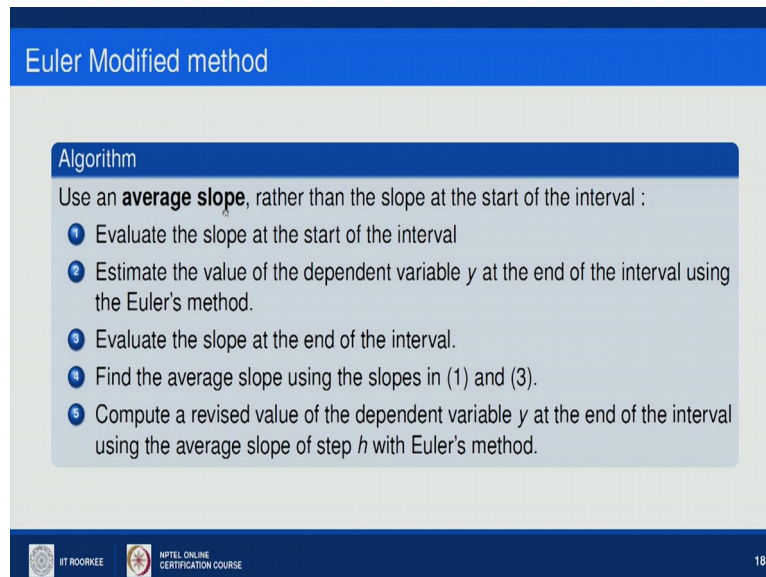

$$\cos x = \sum_{n=0}^{\infty} \frac{(-1)^n}{(2n)!} x^{2n}$$

16

And then substituting in expression I will get this particular 1 minus X square by factorial 2 plus X rest to power 4 upon factorial four and so on. So this was about the Taylor's method and here I told you that we can use quadratic Taylor method which is having the error of order of H square however we can use higher order Taylor method for getting better accuracy.

Now I will explain one more method that is Euler's modified method and that is just an improvement of the Euler's method which we have discussed in earlier lecture and what is this method?

(Refer Slide Time: 18:48)

The slide is titled "Euler Modified method" in a blue header. Below the header, there is a box labeled "Algorithm" with a blue background. The text inside the box reads: "Use an **average slope**, rather than the slope at the start of the interval :". Below this text is a numbered list of five steps:

- 1 Evaluate the slope at the start of the interval
- 2 Estimate the value of the dependent variable  $y$  at the end of the interval using the Euler's method.
- 3 Evaluate the slope at the end of the interval.
- 4 Find the average slope using the slopes in (1) and (3).
- 5 Compute a revised value of the dependent variable  $y$  at the end of the interval using the average slope of step  $h$  with Euler's method.

At the bottom of the slide, there are logos for "IIT ROORKEE" and "NPTEL ONLINE CERTIFICATION COURSE" on the left, and the number "18" on the right.

Basically in this method we will use an average slope rather than the slope at the start of the interval like we have taken the slope at the starting point in of the interval in Euler's method. So what I will do? I will evaluate the slope at the start of the interval, I will estimate the value of the dependent variable  $Y$  at the end of the interval using the Euler's method evaluate the slope at the end of the interval.

Find the average slope using slopes in step 1 and step 3 and compute a revised value of dependent variable  $Y$  at the end of the interval using the average slope of step  $H$  with Euler's method.

(Refer Slide Time: 19:39)

So if I want to explain this method so basically problem is I need to solve this problem by prime equals to f of XY, YX not equals to Y nought. And I want to calculate Y1 which is the value of Y at X nought plus H. So what I have done in the Euler's method I have used Y1 equals to Y0 plus H times FX0, Y0. Where I am approximating the value of Y at X equals to X1 by the slope which I have taken at the initial point of the interval.

For example if this is the function, this is the point X nought, this is the point X1. So here I know the value and I am taking the slope here and I am approximating this value by this one in Euler's method. Here I am calculated this value of Y1 and I will use this as the predict value. Then what I will do? I will correct this predict value by a new formula that will be Y nought plus H times F of X nought Y nought plus F of X1 Y1 star.

So what I am doing using the Euler's method I am finding the slope at the end point of the interval means at this particular point and then what I am doing I am taking the average of the slope over the whole interval by 1 by 2 of these two. And here what I am doing? This formula I can use again and again because this is the corrector formula and this formula I can use again and again in an implicit manner.

How? You can see here I am having Y1 as well as Y1 star, so I will calculate Y1 from this again I will substitute that Y1 here. I will get a new Y1 that is the more better approximation and again and again I will repeat this process and I will get a better approximation. So this

these two formulas jointly is called Euler's modified method. So in first you need to find out a predict value of  $Y_1$  and then you can correct the predict value by this formula.

So in general setting I can write this as  $Y_{n+1}$  is equals to  $Y_n$  plus  $H$  times  $f$  of  $X_n, Y_n$ . If you know the value of  $Y_n$  at  $X$  equals to  $X_n$  and you want to calculate value at  $x$  equals to  $X_n$  plus  $H$  that is  $X_{n+1}$ . So this is predict formula and a corrector formula is  $Y_{n+1}$  equals to  $Y_n$  plus  $H$  upon  $2$   $F$  at  $X_n, Y_n$  plus  $F$  at  $X_{n+1/2}, Y_{n+1/2}$ .

(Refer Slide Time: 23:55)

The slide is titled "Euler Modified method" and contains a section for "Error analysis". It starts with the instruction "Start with  $y_0 = Y$  and at each step, let". The formulas shown are:

$$y'_n := f(x_n, y_n),$$

$$u := y_n + \frac{y'_n}{2},$$

$$u' := f(x_{n+1/2}, u),$$

$$y_{n+1} := y_n + hu'.$$

where  $x_{n+1/2} = x_n + \frac{h}{2}$

The slide footer includes the logos for "BIT ROORKEE" and "NIPTEL ONLINE CERTIFICATION COURSE", along with the page number "21".

So if we talk about error analysis in this modified method so suppose at starting  $y$  at  $F_0$  is given by capital  $Y$  and at each step I am having  $y$  prime  $n$  equals to  $f$  of  $X_n, Y_n$ . That is a given differential equation and  $u$  equals to  $Y_n$  plus  $Y_n$  prime upon  $2$ .  $U$  prime is  $F$   $X_n$  plus  $H$  by  $2$ . So  $X_n$  plus half is basically  $X_n$  plus  $H$  by  $2$ . I am taking the half length of the interval comma  $U$  and finally  $Y_{n+1}$  is given as  $Y_n$  plus  $H$  times  $u$  prime.

(Refer Slide Time: 24:34)

Euler Modified method

Error analysis

Consider

$$y(x_{n+1}) = y(x_n + h) = y(x_n) + hy'(x_n) + \frac{h^2}{2!}y''(x_n) + \mathcal{O}(h^3)$$

$$y'(x_{n+1/2}) = y'(x_n + \frac{1}{2}h) = y'(x_n) + \frac{1}{2}hy''(x_n) + \mathcal{O}(h^2)$$

So

$$y(x_{n+1}) = y(x_n) + hy'(x_{n+1/2}) + \mathcal{O}(h^3)$$

Now,

$$|y'_n - y'(x_n)| = |f(x_n, y_n) - f(x_n, y(x_n))| \leq k|y_n - y(x_n)| = ke_n$$

22

Then if I use the Taylor series expansion of Y about X equals to XN then I can write in this way. If I calculate y prime XN plus half is given by Y prime XN plus half h so that will come in this form. And here you can note down just look at this two terms that are similar so I can substitute this particular thing here. So Y XN plus 1 is given as Y XN plus H time Y primes XN plus half plus order of H cube.

Now the difference between Y prime N and Y prime at XN is given by these two functions and we are assuming that F is Lipchitz continuous with Lipchitz constant K. So I can write in this way and that is equals to K times EN. That is error in (( ))(25:26).

(Refer Slide Time: 25:29)

Euler Modified method

Error analysis

$$|u - y(x_{n+1/2})| = |y_n + \frac{1}{2}hy'_n - y(x_n) - \frac{1}{2}hy'(x_n) + \mathcal{O}(h^2)|$$

$$\leq |y_n - y(x_n)| + \frac{1}{2}h|y'_n - y'(x_n)| + \mathcal{O}(h^2)$$

$$\leq e_n + \frac{1}{2}hke_n + \mathcal{O}(h^2).$$

So,

$$|u' - y'(x_{n+1/2})| = |f(x_{n+1/2}, u) - f(x_{n+1/2}, y(x_{n+1/2}))|$$

$$\leq k|u - y(x_{n+1/2})| \leq k(1 + \frac{1}{2}hk)e_n + \mathcal{O}(h^2)$$

23

So  $U_{n+1} - Y_{n+1}$  can be given now by this particular equation which is less than equal to  $Y_n + Y_{n+1}$ . I have taken this term and this term together plus half  $H$  I have taken common. So  $Y'_n - \frac{1}{2}H$  I have taken out. So  $Y'_n + \text{order of } H^2$  which is  $EN + \frac{1}{2}HK + \text{order of } H^2$ . Similarly I can get  $U'_n - Y'_n + \frac{1}{2}H$  and that is given by  $K \times (1 + \frac{1}{2}HK) + \text{order of } H^2$ .

So finally  $Y_n + 1 - Y_{n+1} + 1$  that is the error in  $n + 1$  step is can be calculated  $Y_n + H \times U'_n - Y_{n+1} - H Y'_n + \frac{1}{2}H^2 + \text{order of } H^3$  that is less than equal to  $Y_n - Y_{n+1} + H \times U'_n - Y'_n + \frac{1}{2}H^2 + \text{order of } H^3$ . So  $EN + 1$  will be less than  $EN + HK$  I have taken common.

So  $1 + \frac{1}{2}KH$  into  $EN$  and these values I have substitute in from the previous slide which I have calculated earlier. So if I take  $\alpha$  equals to  $1 + HK + \frac{1}{2}H^2K^2$  and so on. So after substituting this values and writing the error in (26:57) in terms of error in initial error that is error in the initial iteration.

(Refer Slide Time: 27:01)

Euler Modified method

Error analysis

$$\leq \alpha^n e_0 + ch^3 \frac{(\alpha^n - 1)}{\alpha - 1}$$

$$\leq \alpha^n \left( e_0 + \frac{ch^2}{k} \right)$$

$$\leq e^{kx} \left( e_0 + \frac{ch^2}{k} \right).$$

Thus, the algorithm has error of order  $O(h^2)$ .

BIT ROORKEE    NIPTEL ONLINE CERTIFICATION COURSE    25

Then I will get this particular approximation and again like the quadratic Taylor method this particular approximation and again like the quadratic Taylor method here the algorithm has error of order  $H^2$  which is again an improvement over the simple Euler method that is given error of order  $H$ .

(Refer Slide Time: 27:21)

**Euler Modified method**

**Example**

Solve the problem using the modified Euler method and compare the result with the exact solution  $y^*(x)$ .

$$y'(x) = \frac{2y}{x} + x, \quad x \in [1, 1.4], \quad n = 4, \quad y^*(x) = x^2 + x^2 \ln x$$

26

So after this we will take one example of Euler's modified method so example is given by this particular initial value problem. So  $Y$  prime  $X$  is  $2Y$  upon  $X$  plus  $X$  and I need to find out the value of  $X$  in interval 1 to 1 point 4 by taking  $N$  equals to 4. The same time a  $X$  solution is also given for this particular differential equation which is  $X$  square plus  $X$  square log  $X$  with natural base and now so here if I calculate the initial value of  $Y$  at  $X$  equals to 1, it will be 1.

So  $Y_1$  is 1. I need to calculate  $y$  at 1 point 1,  $y$  at 1 point 2,  $y$  at 1 point 3 and  $y$  at 1 point 4 and at a same time we will compare the approximate value with the exact value and we will see how much error we are getting in our solution. So how to apply this method?

(Refer Slide Time: 28:30)

$y' = \frac{2y}{x} + x, \quad x \in [1, 1.4] \quad y^*(x) = x^2 + x^2 \ln x$   
 $x_0 = 1, \quad y_0 = 1$   
 $x_1 = 1.1, \quad y_1 = ?$   
 $x_2 = 1.2, \quad y_2 = ?$   
 $x_3 = 1.3, \quad y_3 = ?$   
 $x_4 = 1.4, \quad y_4 = ?$

$y_1^* = y_0 + h f(x_0, y_0)$   
 $= 1 + (0.1)(3) = 1.3$   
 $y_1 = y_0 + \frac{h}{2} [f(x_0, y_0) + f(x_1, y_1^*)]$   
 $= 1 + \frac{0.1}{2} \left[ 3 + \frac{2(1.3)}{1.1} + 1.1 \right]$   
 $= 1 + (0.05) \left[ 4.1 + \frac{2.6}{1.1} \right]$

So by initial value problem is given as  $Y' = 2Y$  upon  $X$  plus  $X$ .  $X$  belongs to interval 1 to 1 point 4. So the two solution analytics solution also given that is  $Y^* = X^2 + X^2 \log X$ . Now I need to solve this problem. So here  $X$  nought is 1. So  $Y$  nought is come at this equation I can calculate when  $X$  is 1  $Y$  will become 1.  $X_1$  is 1 point 1.  $Y_1$  I need to calculate.

$X_2$  is 1 point 2,  $Y_2$  I need to calculate.  $X_3$  is 1 point 3,  $Y_3$  I need to calculate and so for  $Y_4$ ,  $X_4$  that is 1 point 4. So let us first calculate  $Y_1$  using the Euler's modified method. So  $Y_1$  is given as  $Y_0 + H \cdot F(X_0, Y_0)$ . So  $Y_0$  is 1 plus  $H$  is point 1 here  $F$  of  $X_0, Y_0$  can be calculated from this because it is my  $F$  of  $XY$ . So 2 upon 1 2 plus 1 3 so it is coming at 1 point 3 and this is the predict value.

Now I will correct this value. So  $Y_1$  will be  $Y_0 + H \cdot (2F(X_0, Y_0) + F(X_1, Y_1^*))$ . So  $Y_0$  is 1 plus  $H$  is point 5 upon 2.  $F$  of  $X_0, Y_0$  is 3 plus  $F(X_1, Y_1^*)$  star will become 2 into 1.3 upon  $X_1$  is 1.1 plus 1.1. So 1 plus sorry it is 4 point 1 point 05 into 4 point 1 plus 2 point 6 upon 1 point 1. So after simplifying this particular expression I will calculate the value of  $Y_1$  that is the value of  $Y$  at  $X$  equals to 1 point 1.

(Refer Slide Time: 31:46)

i	$x_i$	$y_i$	$y_i^*$
0	1.0	1.00000	1.00000
1	1.1	1.32405	1.32533
2	1.2	1.69982	1.70254
3	1.3	2.12905	2.13340
4	1.4	2.61336	2.61949

This value is coming  $Y$  at  $X$  equals to 1 point one is 1 point 32405 where the exact value was 1 point 32533. So a very small difference we are having here that is after third place of decimal. Then  $Y$  at  $X$  equals to 1 point 2 is 1 point 69982. The exact one is 1 point 70254.  $Y$  at  $X$  equals to 1 point 3 is 2 point 12905 exact one is 2 point 13340 and and finally these are the approximate and exact values of  $Y$  at  $X$  equals to 1 point 4.

So here you can note down from these two columns that the approximate solution is quite close to the exact one. And this is the implementation of the Euler's modified method for solving initial value problem. So in this lecture we have seen 2 methods those are having error of order  $H^2$ . That is the quadratic Taylor method and then Euler's modified method.

In the next lecture we will learn another class of numerical methods for solving ordinary differential equation and those methods are called Runge Kutta method. So thank you very much for listening this lecture.
