Lecture - 15
Diagonalizable Matrices

(Refer Slide Time: 00:43)

The image shows handwritten mathematical derivations on a whiteboard. On the left side, the following equations are written:

$$B = P^{-1}AP$$

$$PB P^{-1} = A$$

$$(P^{-1})^{-1} B P^{-1} = A$$

$$B = P^{-1}AP$$

$$B^2 = B B = (P^{-1}AP)(P^{-1}AP)$$

$$= P^{-1}A(P P^{-1})AP$$

$$= P^{-1}A I A P$$

$$= P^{-1}A^2 P$$

On the right side, the following equations are written:

Let $f(x) = a_0 x^n + a_1 x^{n-1} + \dots + a_{n-1} x + a_n$

$$B = P^{-1}AP$$

$$f(B) = a_0 B^n + a_1 B^{n-1} + \dots + a_{n-1} B + a_n I$$

$$= a_0 P^{-1}A^n P + a_1 P^{-1}A^{n-1} P + \dots + a_{n-1} P^{-1} A P + a_n P^{-1} I P$$

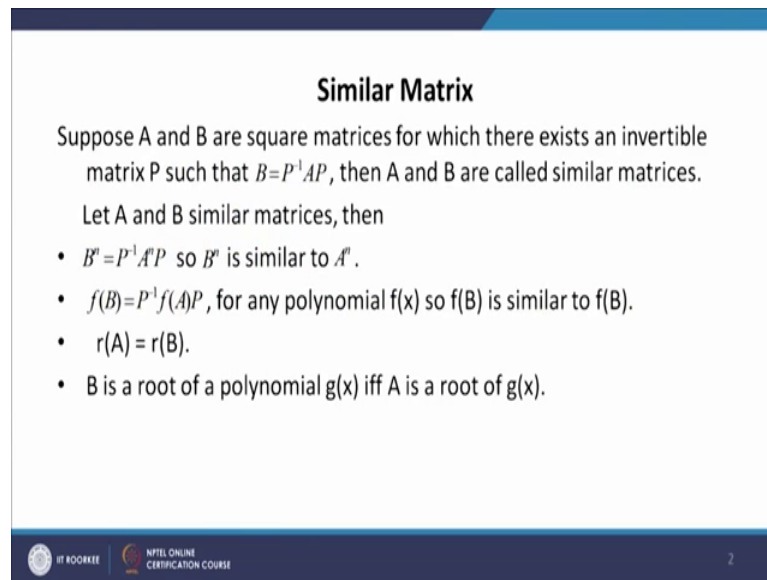

$$= P^{-1} (a_0 A^n + a_1 A^{n-1} + \dots + a_{n-1} A + a_n I) P$$

$$= P^{-1} f(A) P$$

Hello friends, I welcome you to my lecture on diagonalizable matrices. So, let us begin with first be begin with similar matrices. So, let us suppose A and B are square matrices such that we can find a invertible matrix P which can so that we can write B equal to P inverse A P. Suppose A and B are two square matrices of order n, and there is a non singular matrix P such that we can write B equal to P inverse A P. Then we say that we say that B similar to the matrix A.

Now, since we can also write it as P B P inverse equal to A which is same as P inverse inverse B P inverse equal to A. By the definition that B similar to A from here it follows that A similar to B. So, when B similar to A also similar to B and therefore, we say that A and B are similar matrices provided we can find a non similar matrix P such that B is equal to P inverse A P. Now, the similar matrices have very interesting properties.

(Refer Slide Time: 01:49)

Similar Matrix

Suppose A and B are square matrices for which there exists an invertible matrix P such that $B = P^{-1}AP$, then A and B are called similar matrices.

Let A and B similar matrices, then

- $B^n = P^{-1}A^nP$ so B^n is similar to A^n .
- $f(B) = P^{-1}f(A)P$, for any polynomial $f(x)$ so $f(B)$ is similar to $f(A)$.
- $r(A) = r(B)$.
- B is a root of a polynomial $g(x)$ iff A is a root of $g(x)$.

IIIT ROORKEE | NPTEL ONLINE CERTIFICATION COURSE

Suppose A and B are similar matrices then we can see that B to the power n is equal to P inverse a to the power n into P. So, A to the power n and B to the power n are similar matrices, where n is a positive integer. So, let us see we can easily see this suppose A and B are similar then B equal to P inverse A P. So, B into B which is B square this will be equal to P inverse A P to P inverse A P or we can say P inverse A P P inverse A P, P P inverse is identity matrix identity matrix into A will give you a, so we get P inverse A or we can say P inverse A square P.

Similarly, we can prove that P B cube equal to B square into B that is P inverse A square P into P inverse A P and then we will get B cube equal to P inverse A cube P. So, we can by mathematical induction we can say that B to the power n is equal to P inverse A to the power n into P n, so B to the power very similar to A to the power n.

Now, let us show that $f(B)$ is equal to $P^{-1}f(A)P$ for any polynomial $f(x)$. So, we can say that $f(B)$ is similar to $f(A)$. Let us say $f(x)$ is equal to $a_n x^n + a_{n-1} x^{n-1} + \dots + a_1 x + a_0$. Let us take a polynomial in x of degree n and let us assume that A and B are similar matrices, so that B is equal to P inverse A P. Now, we want to prove that $f(B)$ is equal to $P^{-1}f(A)P$. So, $f(B)$ is equal to $a_n B^n + a_{n-1} B^{n-1} + \dots + a_1 B + a_0$ identity matrix of order n. And this is equal to now we have seen that B to the power n is equal to P inverse a to the power n into B, so a naught P inverse A to the

power n into P plus a $1 P^{-1} A$ to the power $n - 1$ into P and so on a $n - 1 P^{-1}$ inverse $A P$. And then we can write a $n P^{-1} I P$ identity matrix is can be written as $P^{-1} I P$.

And then we can write it as $P^{-1} a$ naught is a scalar, I can take it inside. So, a naught A to the power n in to P then a 1 sorry not a $1 P^{-1} a$ A to the power $n - 1$ into P and so on $P^{-1} a$ $n - 1 A$ into P plus $P^{-1} a$ $n I$ into P . Or we can write it as P^{-1} of a naught A to the power n plus a $1 A$ to the power $n - 1$ a $2 A$ to the power $n - 2$ and so on a $n A$ plus no a $n - 1 A$ and then a $n I P$. So, this is nothing but $P^{-1} f A P$. So, $f B$ is equal to P^{-1} of $A P$ and therefore, $f B$ and $f A$ are similar.

Now, let us go to the last one B is a root of the polynomial $r A$ is equal to $r A$, $r A$ is denotes the rank of A , $r B$ is the rank of B . So, when A and B are similar matrices the ranks of A and B are also same, so that we can easily see when A and B are similar matrices, we can write B as $B^{-1} A P$. When you post multiply a matrix by an invertible matrix its rank does not change. So, A is pre multiplied by P^{-1} post multiplied by P which are non similar matrices. So, the rank of A does not change and therefore, rank of $P^{-1} A P$ is same as rank of A , and therefore, rank of B is equal to rank of A .

Now, then we have B is the root of the polynomial $g x$; if A is a root of the polynomial $g x$. So, we can see here if A is a root of $f A$ is a root of f that is $f A$ equal to 0 then A is then B is also root of f . If $f A$ equal to 0 , $f B$ equal to 0 . So, instead of f we can write here g . So, then B is a root of $g x$, then f is a root of $g x$ and so on in conversely.

(Refer Slide Time: 08:03)

• Similar matrices have the same eigenvalues.

• Similar matrices have the same trace.

• Similar matrices have the same determinant.

IT ROORKEE | NPTEL ONLINE CERTIFICATION COURSE

Now, we go to a similar matrices have the same eigenvalues.

(Refer Slide Time: 08:15)

$B = P^{-1}AP$

The characteristic polynomial of the matrix B is

$$|B - \lambda I|$$
$$= |P^{-1}AP - \lambda I|$$
$$= |P^{-1}AP - \lambda P^{-1}IP|$$
$$= |P^{-1}AP - P^{-1}(\lambda I)P|$$
$$= |P^{-1}(A - \lambda I)P| = |P^{-1}| |A - \lambda I| |P| = |A - \lambda I| = \text{Characteristic polynomial of } A$$

$P^{-1}P = I$

$$|P^{-1}P| = |I| = 1$$
$$|P^{-1}| |P| = 1$$

So, let A and B be similar matrices then B are given that B is equal to P inverse A P. We shall prove that the two matrices A and B have the same constructive polynomial. And from there it will follow that they have same eigenvalues. And the characteristic polynomial of a matrix A is given by determinant of A minus lambda I. So, let us write the characteristic polynomial for the matrix B. The characteristic polynomial of the matrix B is determinant of B minus lambda I, which we can write as P inverse A P minus

λI . And this I can also write as determinant of $P^{-1}(A - \lambda I)P$. Now, which is same as determinant of $P^{-1}A - \lambda I$.

Now, if A and B are two square matrices of the same order, then determinant of AB is equal to determinant of A into determinant of B . So, we can write this as determinant of $P^{-1}AP$ into determinant of $A - \lambda I$ into determinant of P . This is equal to determinant of P^{-1} into determinant of $A - \lambda I$ into determinant of P . Now, P into P^{-1} are P^{-1} into P is an identity matrix ok. So, determinant of $P^{-1}P$ is equal to determinant of I which is equal to 1. Now this is determinant of P^{-1} into determinant of P which is equal to 1.

So, determinant of P^{-1} into determinant of P that is equal to 1; we can interchange the position here where real quantities. So, we have determinant of $A - \lambda I$ into determinant of P into determinant of P^{-1} is equal 1. So, we have determinant of $A - \lambda I$, which is the characteristic polynomial of A . So, the two matrices if they are similar have same characteristic polynomial, and therefore, they have same roots. So, we have they have same Eigen values.

Now, similar matrices have the same trace. This follows from the previous result, similar matrices have the same Eigen values, and therefore, they have same trace because trace of a matrix is the sum of the Eigen values. So, they have same trace and then we have similar matrices have the same determinant.

(Refer Slide Time: 11:52)

$$B = P^{-1} A P$$
$$|B| = |P^{-1}| |A| |P| = |A|$$
$$A = \begin{bmatrix} 0 & 1 \\ -1 & 0 \end{bmatrix}$$
$$|A - \lambda I| = \begin{vmatrix} -\lambda & 1 \\ -1 & -\lambda \end{vmatrix} = \lambda^2 + 1$$
$$|A - \lambda I| = 0 \Rightarrow \lambda = \pm i$$
$$P^{-1} P = I$$
$$|P^{-1} P| = |I| = 1$$
$$|P^{-1}| |P| = 1$$

This also follows easily B is equal to P inverse A P. So, you take the determinant of B that is equal to determinant of P inverse A P which is determinant of P inverse into determinant of A into determinant of P as we have seen determinant of P into determinant of P inverse is equal to 1. So, this is determinant of A. So, similar matrices have the same determinate. Ah now comes the question of diagonalization, the diagonalization of A square matrix is very important concept; it is very useful in the study of bilinear forms.

(Refer Slide Time: 12:38)

Diagonalization

A square matrix A is called diagonalizable if there is an invertible matrix P such that $P^{-1} A P$ is a diagonal matrix (i.e. $P^{-1} A P = D$).

Theorem: If A is an $n \times n$ matrix, then the following are equivalent

- A is diagonalizable.
- A has n linearly independent eigenvectors.

IF PGOORKEE | NPTEL ONLINE CERTIFICATION COURSE

So, let us see how we can diagonalize a given matrix. A square matrix is called diagonalizable if we can find an invertible matrix P such that $P^{-1}AP$ is a diagonal matrix. Now, not all real square matrices are diagonalizable. There are many examples of real square matrices, which are not diagonalizable. In fact, you can find a real square matrix which does not have any real eigen value. Say for example, you can take the matrix A equal to $\begin{pmatrix} 0 & -1 \\ 1 & 0 \end{pmatrix}$. Let us consider this matrix.

Then determinant of $A - \lambda I$ is equal to $\det \begin{pmatrix} -\lambda & -1 \\ 1 & -\lambda \end{pmatrix} = \lambda^2 + 1$. So, this is this will be I think I should take one here, this is this is one, then that we are like let me write (Refer Time: 13:40) take the matrix like this A equal to $\begin{pmatrix} 0 & -1 \\ 1 & 0 \end{pmatrix}$, so $\det(A - \lambda I) = \lambda^2 + 1$ like this. So, this equal to $\lambda^2 + 1$. So, determinant of $A - \lambda I = 0$ gives you $\lambda = \pm i$.

So, there exist matrices which do not have real eigen values, but we have but there are type of matrices for which the diagonalization is always there says d l c symmetric matrix. If you take a real symmetric matrix then it is always diagonalizable; in fact, we can find a an orthogonal matrix P such that $P^{-1}AP$ is a diagonal matrix. And one P is orthogonal matrix P^{-1} is equal to P^T . So, when a real symmetric matrix we have, then it is always diagonalizable; and there we find an orthogonal matrix P such that $P^{-1}AP$ is a diagonal matrix, so that come that point will come later.

Let us first see for an arbitrary matrix when it will be diagonalizable. So, it will diagonalizable if we can find a invertible matrix P such that $P^{-1}AP$ is a diagonal matrix. And the necessary and sufficient condition for the diagonalizability of a n by n matrices that it must have n linearly independent eigen vectors.

(Refer Slide Time: 15:11)

Diagonalization

A square matrix A is called diagonalizable if there is an invertible matrix P such that $P^{-1}AP$ is a diagonal matrix (i.e. $P^{-1}AP = D$).

Theorem: If A is an $n \times n$ matrix, then the following are equivalent

- A is diagonalizable.
- A has n linearly independent eigenvectors.

So, A is diagonalizable if and only if A has n linearly independent eigenvectors. Now let us prove this results.

(Refer Slide Time: 15:19)

$\text{or } P^{-1}AP = D \Rightarrow A \text{ is diagonalizable.}$
 $A \text{ is diagonalizable} \Leftrightarrow A \text{ has } n \text{ linearly independent eigen vectors}$
 Let A have n linearly independent eigen vectors
 then we have to prove that A is diagonalizable
 Let v_1, v_2, \dots, v_n be the n linearly independent eigen
 vectors of A corresponding to the eigen values $\lambda_1, \lambda_2, \dots, \lambda_n$ of A .
 Then $Av_1 = \lambda_1 v_1, Av_2 = \lambda_2 v_2, \dots, Av_n = \lambda_n v_n$
 Let us define $P = [v_1 \ v_2 \ \dots \ v_n]$
 $r(P) = n \Rightarrow |P| \neq 0 \Rightarrow P$ is invertible
 $AP = A[v_1 \ v_2 \ \dots \ v_n] = [Av_1 \ Av_2 \ \dots \ Av_n] = [\lambda_1 v_1 \ \lambda_2 v_2 \ \dots \ \lambda_n v_n] = [v_1 \ v_2 \ \dots \ v_n] \begin{bmatrix} \lambda_1 & 0 & \dots & 0 \\ 0 & \lambda_2 & \dots & 0 \\ \vdots & \vdots & \ddots & \vdots \\ 0 & 0 & \dots & \lambda_n \end{bmatrix}$
 $= PD$

So, we are going to prove that A is diagonalizable if and only if A has n linearly independent eigenvectors, where this n is the order of the matrix. We are considering A to be a square matrix of order n . Now, so let us first assume that let A have n linearly independent eigenvectors then we should we have to prove that A is diagonalizable . So, let us say let v_1, v_2, v_n be v eigenvectors of A be the n linearly independent eigenvectors of A corresponding to the eigenvalues λ_1, λ_2 and so on λ_n of A . Then we have the matrix equation then $Ax = \lambda_1 x$ equal to sorry $Av_1 = \lambda_1 v_1$ equal to

$\lambda_1 v_1, \lambda_2 v_2$ and so on, $A v_n = \lambda_n v_n$.

Now, what do you do is that we have n linearly independent eigenvectors from these n eigenvectors. Let us form the matrix P whose columns are these n eigenvectors. So, let us define P to be equal to let us form the matrix P with these n eigenvectors. Since, v_1, v_2, \dots, v_n all are linearly independent the matrix P has n linearly independent columns. So, its column rank is equal to n and so rank of the matrix P is equal to n . So, rank of P is equal to n which means that P is a non singular matrix ok. So, determinant of P is determinant of P is not equal to 0, and which implies that P is invertible.

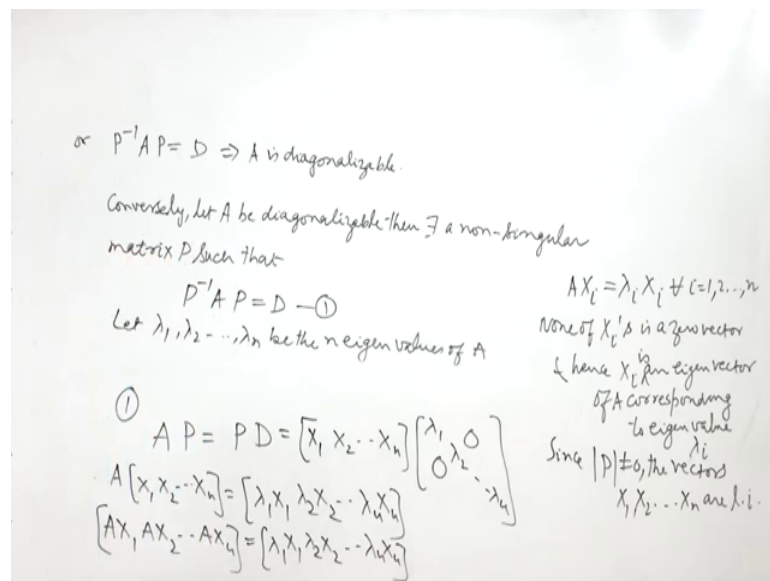

Now, what we do is let us consider A into P matrix. So, A into P matrix is what A matrix multiplied by v_1, v_2 and so on v_n . When you multiply the matrix A by P , what you do, you multiply the rows of A by the first column to get the first column of AP . So, when you multiply the rows of A by v_1 , v_1 is the first column of the matrix P , but you get the first column as $A v_1$. Similarly, you multiply by the second column v_2 of the matrix P to all the rows of A , you get $A v_2$ column second column. And then similarly we get last column $A v_n$ which is an n by n matrix.

Now, $A v_1 = \lambda_1 v_1, A v_2 = \lambda_2 v_2$. So, we get $\lambda_1 v_1, \lambda_2 v_2$ and so on $\lambda_n v_n$. The right hand side this is nothing but v_1, v_2, \dots, v_n that is the matrix P multiplied by the diagonal matrix $\lambda_1 \ 0 \ 0 \ 0 \ \lambda_2 \ 0 \ 0 \ 0 \ \dots$ which is diagonal matrix. First column of this diagonal matrix is $\lambda_1 \ 0 \ 0 \ 0 \ 1$. You multiply by this column to v_1 vector, you get $\lambda_1 v_1$. And when you multiply second column to v_2 vector you get $\lambda_2 v_2$ and so on. So, we can write like that.

And this is nothing but then this is P and that has defined it by D . So, we get $AP = PD$. So, $AP = PD$ or we can say $P^{-1}AP = D$ because $P^{-1}AP$ is equal to D , where D is the diagonal matrix. So, we have found a matrix invertible matrix P such that $P^{-1}AP = D$. So, A is similar to the diagonal matrix and eigenvalues of the similar matrices are same which we have already seen. So, eigenvalues of A are $\lambda_1, \lambda_2, \dots, \lambda_n$. So, eigenvalues of the diagonal matrix are also $\lambda_1, \lambda_2, \dots, \lambda_n$ and since the eigenvalues of a diagonal matrix are its diagonal entries, so $\lambda_1, \lambda_2, \dots, \lambda_n$ where occur the diagonal of this diagonal matrix.

And they occur in the same order in which you have written the matrix P. First column here is the eigenvector v_1 . So, in the first column there you have the eigen values λ_1 second column is the eigenvector v_2 you have the second eigen value λ_2 there. Last column is the eigenvector v_n , so you have the eigen value λ_n there in the last column. So, now this implies that A is diagonalizable. Now, let us prove the converse. Let us assume that A is diagonalizable and then we show that A has n linearly independent eigenvectors.

(Refer Slide Time: 23:05)

So, conversely let A B diagonalizable, A B diagonalizable. Then there exist a non-singular matrix P such that P inverse A P equal to D. Now, let us say that $\lambda_1, \lambda_2, \lambda_n$ be the eigen values of A; and v_1, v_2, v_n be the eigen corresponding the eigenvectors ok. So, let $\lambda_1, \lambda_2, \lambda_n$ be the an eigen values of a and v_1, v_2, v_n be the corresponding eigenvectors. So, what will happen P inverse A P or I can say this equation 1. One is nothing but A P equal to P D, A P equal to PD.

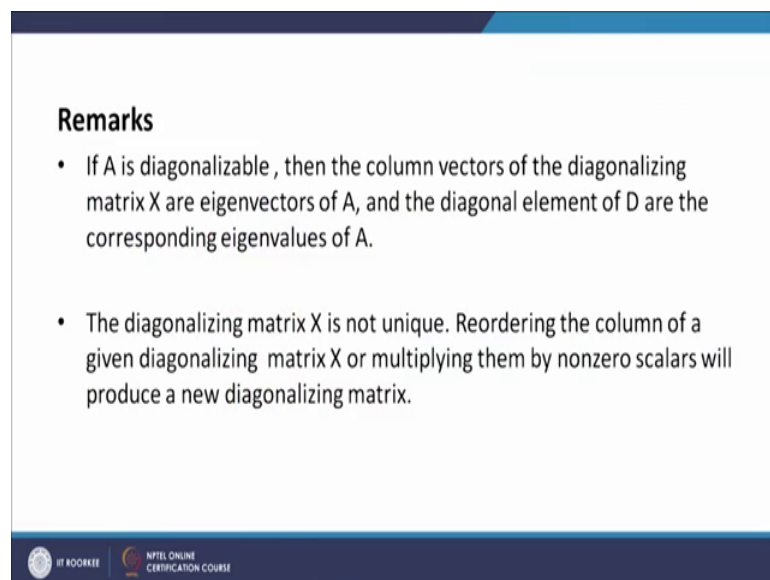

So, what we will have here this is nothing but P matrix let us say the columns of P are wait, wait let us say not like this. Let us assume that $\lambda_1, \lambda_2, \lambda_n$ be the an eigen values of A, we shall find their eigenvectors. So, A P equal to P D, then P suppose has columns x_1, x_2, x_n ; and D has $\lambda_1, \lambda_2, \lambda_n$ they are the eigenvalues of A. And here what will have left side will be A x_1, x_2 and so on x_n . So, when you multiply this diagonal matrix to this P matrix, what we will get $\lambda_1 x_1,$

$\lambda_2 \times 2$ and so on $\lambda_n \times n$. Left hand side will give you $A x_1, A x_2, A x_n$ here first column is $A x_1$ second column is $A x_2$ and so on. So, what we have by the equality of two matrices $A x_1$ equal to $\lambda_1 x_1, A x_2$ equal to $\lambda_2 x_2, A x_n$ equal to $\lambda_n x_n$. Or we can say $A x_i$ equal to $\lambda_i x_i$ for all i equal to 1, 2, 3 and so on up to n . And therefore, for the Eigen value λ_i, X_i is the eigenvector ok.

So, now one one one thing more none of the X_i is can be 0, because X_i if it is 0 then P matrix will be have determinant 0, and we have assume that P is non-singular. So, none of the X_i is a 0 vector. And this equation and hence X_i is an eigenvector of A corresponding to Eigen value λ_i , corresponding to Eigen value λ_i .

So, what we have corresponding to the Eigen values λ_1, λ_2 we have found n Eigen vectors which are x_1, x_2, x_3 and so on x_n . And the matrix P whose columns are x_1, x_2, x_n is non-singular. So, therefore, the A n eigenvectors are linearly independent. So, since determinant of P is nonzero, the vectors x_1, x_2 and so on x_n are linearly independent. So, A has n linearly independent eigenvectors corresponding to the eigenvalues $\lambda_1, \lambda_2, \lambda_n$.

(Refer Slide Time: 28:35)

Remarks

- If A is diagonalizable, then the column vectors of the diagonalizing matrix X are eigenvectors of A , and the diagonal element of D are the corresponding eigenvalues of A .
- The diagonalizing matrix X is not unique. Reordering the column of a given diagonalizing matrix X or multiplying them by nonzero scalars will produce a new diagonalizing matrix.

IT ROOBBEE | NPTEL ONLINE CERTIFICATION COURSE

Now, let us make some remarks if A is diagonalizable then the column vectors of the diagonalizable diagonalizing matrix X , here I have written X , but it it is any matrix you can write P they are the eigenvectors of A . So, the diagonalizing matrix, the columns of the diagonalizing matrix are the eigenvectors of A , and the diagonal elements of D are

the eigen values of the corresponding Eigen values of the matrix as I said. The diagonalizing matrix is not unique, because you can write the an eigen vectors as its columns in any order. In whatever order you write them in the same order the eigenvalues will be written in the diagonal matrix. So, the diagonalizing matrix x is not unique. Reordering the columns of a given diagonalizing matrix or multiplying them by nonzero scalars will produce a new diagonalizing matrix ok.

(Refer Slide Time: 29:32)

Example: Find a matrix P that diagonalizes

$$A = \begin{pmatrix} 4 & 1 & -1 \\ 2 & 5 & -2 \\ 1 & 1 & 2 \end{pmatrix}$$

Solution: The characteristic polynomial of the matrix

$$\det(\lambda I - A) = \begin{vmatrix} \lambda - 4 & 1 & -1 \\ 2 & \lambda - 5 & -2 \\ 1 & 1 & \lambda - 2 \end{vmatrix} = (\lambda - 3)^2(\lambda - 5)$$

Now, let us find a matrix P that diagonalizes this matrix A. So, is 4 1 minus 1 2 5 minus 2 1 1 2. When we find the characteristic polynomial of this matrix, it is a cubic equation in lambda the determinant of lambda I minus A will come out to be a cubic equation whose vectors are lambda minus 3 whole square into lambda minus 5. So, the eigenvalues of the matrix A are lambda equal to 3, which occurs twice that is its algebraic multiplicity is 3, algebraic multiplicity is 2, and lambda is equal to 5 which occurs once. Now, for the eigenvalue lambda equal to 3, let us find the Eigen vectors.

(Refer Slide Time: 30:03)

For the eigenvalue $\lambda = 3$, the eigenvectors are

$$p_1 = \begin{pmatrix} 1 \\ -1 \\ 0 \end{pmatrix} \quad p_2 = \begin{pmatrix} 1 \\ 0 \\ 1 \end{pmatrix}$$

For the eigenvalue $\lambda = 5$, the eigenvector is

$$p_3 = \begin{pmatrix} 1 \\ 2 \\ 1 \end{pmatrix}$$

IT ROORKEE | NPTEL ONLINE CERTIFICATION COURSE 7

So, we have here the eigen the matrix as 4 1 minus 1.

(Refer Slide Time: 30:12)

$$P = \begin{bmatrix} 1 & -1 & 1 \\ 0 & 1 & 2 \\ 1 & 0 & 1 \end{bmatrix} \rightarrow \text{Modal matrix}$$

$$A = \begin{bmatrix} 4 & 1 & -1 \\ 2 & 5 & -2 \\ 1 & 1 & 2 \end{bmatrix}$$

$\lambda = 3, 3, 5$

Eigen vector for $\lambda = 3$:

$$(A - 3I)x = 0$$
$$\begin{bmatrix} 1 & 1 & -1 \\ 2 & 2 & -2 \\ 1 & 1 & -1 \end{bmatrix} \begin{bmatrix} x_1 \\ x_2 \\ x_3 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \\ 0 \end{bmatrix}$$

or $\begin{bmatrix} 1 & 1 & -1 \\ 0 & 0 & 0 \\ 0 & 0 & 0 \end{bmatrix} \begin{bmatrix} x_1 \\ x_2 \\ x_3 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \\ 0 \end{bmatrix}$

$(\Rightarrow) x_1 + x_2 - x_3 = 0$
or $x_1 = x_3 - x_2$

So, $x = \begin{bmatrix} x_1 \\ x_2 \\ x_3 \end{bmatrix} = \begin{bmatrix} x_3 - x_2 \\ x_2 \\ x_3 \end{bmatrix}$
 $= x_3 \begin{bmatrix} 1 \\ 0 \\ 1 \end{bmatrix} + x_2 \begin{bmatrix} -1 \\ 1 \\ 0 \end{bmatrix}$

A is equal to 4 1 minus 1, and then we have 2 5 minus 2, and third row is 1 1 2 lambda eigen values are 3 3 5. So, algebraic multiplicity of lambda equal to 3 is 2. Now, eigenvector for lambda equal to 3 let us find so, A minus 3 I x equal to 0. So, if let us subtract 3 from diagonal elements of A, so we will get 1 1 minus 1 then 2 2 minus 2 then 1 1 minus 1. Let us say the components of x are x 1, x 2 x 3; and zero matrix is 0 0 0 column matrix. So, when you multiply this by 2 and subtract here this will become 0;

when you subtract first row from the third row, this will also become 0. So, this system of equations is same as $x_1 + x_2 - x_3 = 0$. The three equations reduce into a single equation, we get $x_1 + x_2 - x_3 = 0$.

Now, I can write it as $x_2 = x_3 - x_1$. So, x_2 is equal to $x_3 - x_1$. x_3 , I can write it as $x_3 = x_2 + x_1$. So, I can write it as linear combination of two vectors $x_3 = 1 \cdot x_1 + 1 \cdot x_2$, and then $x_2 = -1 \cdot x_1 + 0 \cdot x_3$. So, there are two linearly independent eigenvectors they are $\begin{bmatrix} 1 \\ 0 \\ 1 \end{bmatrix}$ and $\begin{bmatrix} -1 \\ 1 \\ 0 \end{bmatrix}$. And for $\lambda = 5$ we considering find $\lambda = 5$, so the algebraic multiplicity of $\lambda = 5$ is 1 geometric multiplicity is also 2. And I had said in my last lecture geometric multiplicity never achieves the algebraic multiplicity, they are equal here.

Now, so and for the λ similarly if you find the Eigen vectors for $\lambda = 5$ it will come out to be $\begin{bmatrix} 1 \\ 2 \\ 1 \end{bmatrix}$. Here the vectors are $\begin{bmatrix} 1 \\ -1 \\ 0 \end{bmatrix}$, and $\begin{bmatrix} 1 \\ 0 \\ 1 \end{bmatrix}$, I have written $\begin{bmatrix} -1 \\ 1 \\ 0 \end{bmatrix}$. If you take instead of $x_2 - x_2$ here then it will be $\begin{bmatrix} 1 \\ -1 \\ 0 \end{bmatrix}$. So, they are same things. So, this is how we can find the eigenvectors for the given matrix and then be formed the matrix P ok. So, P matrix be formed from the eigenvectors of the given matrix. So, suppose I write $\begin{bmatrix} 1 \\ 0 \\ 1 \end{bmatrix}$ as the first column second column as $\begin{bmatrix} -1 \\ 1 \\ 0 \end{bmatrix}$, and third column as the eigenvector for $\lambda = 5$, which is $\begin{bmatrix} 1 \\ 2 \\ 1 \end{bmatrix}$, then this will mat this matrix will diagonalize A this matrix is also called as model matrix.

(Refer Slide Time: 34:09)

$$P = \begin{bmatrix} 1 & -1 & 1 \\ 0 & 1 & 2 \\ 1 & 0 & 1 \end{bmatrix} \rightarrow \text{Model matrix}$$

$$P^{-1} A P = \begin{bmatrix} 3 & 0 & 0 \\ 0 & 3 & 0 \\ 0 & 0 & 5 \end{bmatrix} = D$$

$$A = P D P^{-1}$$

Then

$$A^n = P D^n P^{-1} = P \begin{bmatrix} \lambda_1^n & & 0 \\ & \lambda_2^n & \\ 0 & & \ddots \\ & & & \lambda_n^n \end{bmatrix} P^{-1}$$

And when we will find $P^{-1}AP$ we can verify very easily you can find P^{-1} here. And then if you find $P^{-1}AP$, it will come out to be the diagonal matrix where in the first column we will have the Eigen value corresponding to the first eigenvector which is 3. Then in the second column the Eigen value corresponding to the second eigenvector which is again 3 and in the third column the eigenvector corresponding to the 3, third eigenvector which is 5. So, $P^{-1}AP$ will be equal to this diagonal matrix. So, here diagonalize matrix we have found and also we have found this is D . Now, this diagonalization can be used to find the powers of the matrix A .

So, suppose you are given the matrix A you want to find A to the power k , I can write here A equal to PDP^{-1} , $P^{-1}P$ equal to D . So, $P^{-1}P$ multiply $P^{-1}P$ will become identity and here we will get $P^{-1}A$. So, A^k will be equal to $P^{-1}D^kP$ then I post multiply by P we will get A^k equal to $P^{-1}D^kP$. So, this then A to the power n equal to $P^{-1}D^nP$ we have earlier seen when A and B are similar matrices A to the power n and B to power n are also similar. So, A to the power n is equal to $P^{-1}D^nP$ and D . D has eigenvalues same as eigenvalues of A . So, $P^{-1}A^nP$, λ_1^n , λ_2^n , λ_3^n and we have 0 here ok.

So, in order to find A to the power n , we need to find the matrix for the matrix A , we need to find simply P matrix. And then you can find any power of A , say A to the power 10 or A to the power 100, even we can find A to the power 100. We have taken an example in the previous lecture, we are we have taken a 2 by 1 matrix and we found A to the power 100 that A to the power 100 can also be found here can also be found here very easily by following this diagonalization process.

(Refer Slide Time: 36:56)

Example: Examine the following matrix for diagonalization

$$A = \begin{pmatrix} 1 & 0 & 0 \\ 1 & 2 & 0 \\ -3 & 5 & 2 \end{pmatrix}$$

Solution: The characteristic polynomial of A is

$$\det(\lambda I - A) = \begin{vmatrix} \lambda - 1 & 0 & 0 \\ -1 & \lambda - 2 & 0 \\ 3 & -5 & \lambda - 2 \end{vmatrix} = (\lambda - 1)(\lambda - 2)^2$$

IT ROORKEE | NPTEL ONLINE CERTIFICATION COURSE 9

Now, let us take an example of a matrix where we shall see that the matrix is not diagonalizable. So, here we have an example of a real matrix A equal to $\begin{pmatrix} 1 & 0 & 0 \\ 1 & 2 & 0 \\ -3 & 5 & 2 \end{pmatrix}$. If we write the characteristic polynomial of this matrix and factorize it, we will have the factors $(\lambda - 1)(\lambda - 2)^2$. So, $\lambda = 1$ is an eigenvalue and $\lambda = 2$ is an eigenvalue that occurs twice.

(Refer Slide Time: 37:13)

The bases for the eigenspaces are

$$\text{for } \lambda = 1, p_1 = \begin{pmatrix} 1 \\ 8 \\ -1 \\ 8 \\ 1 \end{pmatrix} \text{ and for } \lambda = 2, p_2 = \begin{pmatrix} 0 \\ 0 \\ 0 \\ 1 \end{pmatrix}$$

Since there are only two basis vectors, A is not diagonalizable.

IT ROORKEE | NPTEL ONLINE CERTIFICATION COURSE 10

And then if you find the eigenvectors for $\lambda = 1$, it turns out that the eigenvector is $p_1 = \begin{pmatrix} 1 \\ 8 \\ -1 \\ 8 \\ 1 \end{pmatrix}$. You can also write it as $\begin{pmatrix} 1 \\ 8 \\ -1 \\ 8 \\ 1 \end{pmatrix}$.

minus 1 and 8 because n is scalar multiple nonzero scalar multiple of an eigenvector is also eigenvector. But in the case of λ is equal to 2 only one eigenvector we get 0 0 1. So, the total number of eigenvectors here are only two while the matrix is of order three. So, we do not have three linearly independent eigenvectors. And therefore, the theorem says A cannot be diagonalizable, because the theorem says that A is diagonalizable if and only if we have three linearly independent eigenvectors.

(Refer Slide Time: 38:10)

$$A = \begin{bmatrix} 1 & 0 & 0 \\ 1 & 2 & 0 \\ -3 & 5 & 2 \end{bmatrix}$$

$$\lambda = 2$$

$$(A - 2I)x = 0$$

$$\begin{bmatrix} -1 & 0 & 0 \\ 1 & 0 & 0 \\ -3 & 5 & 0 \end{bmatrix} \begin{bmatrix} x_1 \\ x_2 \\ x_3 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \\ 0 \end{bmatrix}$$

$$\begin{bmatrix} 0 & 0 & 0 \\ 1 & 0 & 0 \\ 0 & 5 & 0 \end{bmatrix} \begin{bmatrix} x_1 \\ x_2 \\ x_3 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \\ 0 \end{bmatrix}$$

$$x_1 = 0$$

$$x_2 = 0$$

$$x = \begin{bmatrix} x_1 \\ x_2 \\ x_3 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \\ x_3 \end{bmatrix} = x_3 \begin{bmatrix} 0 \\ 0 \\ 1 \end{bmatrix}$$

So, here let me see show you how we get a corresponding to λ equal to 2, only one eigenvector. I would like to show that. So, A is 1 0 0 and then we have $A - 2I$ 1 2 0, and then we have minus 3 5 2. For the eigenvalue λ equal to 2 let us see find the eigenvector. So, λ is equal to 2. So, $A - 2I x = 0$ will give you $A - 2I$ 1 0 0 1, we are subtracting 2, so 0 0 and then we are subtracting 2, so minus 3 and we have 5 here and we have 0 here.

So, what do we get x_1, x_2, x_3 equal to. If I add this second row to the first row first row becomes zero row, adding first second row to the first row. And adding three times the second row to the third row makes it 1 0 0, and this we are adding three times the second row to the third row, so 0 5 0. So, the given system of equations is by linear elementary row operations we have reduced to this system.

So, what we have first row equation is a 0 equation. Second equation says that $x_1 = 0, x_2 = 0, x_3 = 0$. And third equation is give us $x_2 = 5x_3$ equal to 0, wait this

is x_1 ok. Second equation gives x_1 equal to 0, x_2 equal to 0. Third equation gives you x_2 equal to 0; you see $5x_2$ equal to 0. So, x_2 is equal to x_1 , x_2 , x_3 . So, this is equal to 0, 0, x_3 , and therefore, it is scalar multiple of $\begin{bmatrix} 0 \\ 0 \\ 1 \end{bmatrix}$ vector. So, here corresponding to the repeated eigenvalue $\lambda = 2$, we have only one eigenvector. So, geometric multiplicity is 1, by algebraic multiplicity is 2. So, we do not have three eigenvectors and therefore, this matrix is not diagonalizable. So, so this is what we have.

(Refer Slide Time: 40:52)

Computing powers of Matrix A

If A is diagonalizable, then A can be factored into a product XD^{-1} .

$$A^k = XD^kX^{-1}$$

$$= X \begin{pmatrix} \lambda_1^k & & & \\ & \lambda_2^k & & \\ & & \ddots & \\ & & & \lambda_n^k \end{pmatrix} X^{-1}.$$

11

And as I said when A is diagonalizable, we can find any integer power of A , A to the power k is equal to $X D^k X^{-1}$, so that is what I have to say in this lecture.

Thank you very much.
