Lecture - 54
Householder QR factorization – II

Hello friends, welcome to this lecture. And here in this lecture we start we continue our study of QR decomposition. In if you recall in previous lecture we have discussed the QR decomposition of a square matrix.

It means that given a square matrix we need to find out we need to decompose a matrix a into Q into R where this Q is an orthogonal matrix and R is the upper triangular matrix. And we try to show in this lecture; we will show that, that such a representation of a square matrix is unique. And once and once the uniqueness is proven, then we are try to find out that how to find out the QR decomposition of a non square matrix that is a rectangular matrix.

So, that is the content of our this lecture. So, first let us consider the uniqueness problem. So, uniqueness problem means given a matrix A; which is a square matrix we have this representation Q into R.

(Refer Slide Time: 01:17)

Now, we say that suppose we have two representation; $Q_1 R_1$ and $Q_2 R_2$. Then we want to show that this is possible only when, when Q_1 is equal to Q_2 and R_1 is equal to R_2 . It means that Q_1 is same as Q_2 and R_1 is same as R_2 . So, it means that QR decomposition of in square matrix is unique.

So, but before proving this uniqueness result; we need one result that is if a matrix is both upper triangular matrix and orthogonal matrix. Then P has the form. P^2 equal to I . So, that is our result which we are going to use to prove the uniqueness part.

(Refer Slide Time: 02:15)

Uniqueness of QR factorization

Theorem 2
Let P be a real $n \times n$ matrix. If P is both upper triangular and orthogonal, then P has the form

$$P = \begin{bmatrix} \pm 1 & 0 & 0 & 0 & 0 \\ 0 & \pm 1 & 0 & 0 & 0 \\ 0 & 0 & \pm 1 & 0 & 0 \\ 0 & 0 & 0 & \pm 1 & 0 \\ 0 & 0 & 0 & 0 & \pm 1 \end{bmatrix}$$

i.e. P is a diagonal matrix such that $P^2 = I$.

17

So, first let us prove this result; that if we have a; a let P be a real n cross n matrix; If P is both upper triangular and orthogonal matrix. Then P has a form this P is a scalar matrices a scalar matrix where a diagonal entries are plus minus 1 or you can say that P is a diagonal matrix such that P^2 is equal to I . And we try to prove this theorem with the help of mathematical induction, we can prove this without mathematical induction, but this is the best way to prove this theorem.

So, we prove this lemma by induction. So, if n equal to 1 this addition holds trivially. So, 1 means your P is nothing but this. P is equal to 1 here, if I consider this P as a some a here. Now, if P is upper triangle that is ok, but if it is orthogonal means your a square has to be 1. So, it means that P is an scalar matrix such that P^2 is your identity matrix.

(Refer Slide Time: 03:21)

Proof. We prove this lemma by induction. If $n = 1$, the assertion holds trivially. If $n = 2$, let

$$P = \begin{bmatrix} x & y \\ 0 & z \end{bmatrix}$$

Since P is orthogonal, we have $P^T P = I$. Therefore,

$$P^T P = \begin{bmatrix} x^2 & xy \\ xy & y^2 + z^2 \end{bmatrix} = I = \begin{bmatrix} 1 & 0 \\ 0 & 1 \end{bmatrix}$$

Thus, we must have

$$x^2 = 1, xy = 0 \text{ and } y^2 + z^2 = 1 \tag{4}$$

Since $x^2 = 1$, x is nonzero. Hence,

$$xy = 0 \Rightarrow y = 0$$

Thus, the equations in (4) simplify to

$$x^2 = 1, y = 0 \text{ and } z^2 = 1$$

18

So, here for n equal to 1 this is correct. Now, let us show that for n equal to 2. So, for n equal to 2, let P is equal to $\begin{bmatrix} x & y \\ 0 & z \end{bmatrix}$; because it has upper triangular matrix. So, that is why we have taken this form. And we want to show that this y entries is 0 and x and z is of the form that x square and z square is equal to 1.

So, here to show that this y is 0 or x and z the square root of 1. We use this result that P is an orthogonal matrix. So, P transpose P is given as I . So, let us calculate P transpose P . So, P transpose P is basically $\begin{bmatrix} x^2 & xy \\ xy & y^2 + z^2 \end{bmatrix}$. And we know that P transpose P is I that is $\begin{bmatrix} 1 & 0 \\ 0 & 1 \end{bmatrix}$. So, it means that x square is 1, xy is 0 and y square plus z square is equal to 1. So, we have these three relation that x square is equal to 1, xy is equal to 0 and y square plus z square is equal to 1.

Now, we have this x square is equal to 1. So, this implies that x cannot be a nonzero quantity. So, it means that if x is nonzero quantity; then xy equal to 0 possible only when, when we have y equal to 0. So, the first two relation gives you that x is the square root of 1 and y is equal to 0. So, once we have y equal to 0 then the last relation says that your z squared has to be 1. So, it means that this equation these three equation given as an equation number 4 is now, reduced to x square is equal to 1, y equal to 0 and z square equal to 1.

So, it means that the diagonal entries are either plus 1 or minus 1 and the off diagonal entries are simply 0. So, it means that for n equal to 2 we have shown that our result follows.

(Refer Slide Time: 05:18)

Thus, P is a diagonal matrix such that

$$P^2 = \begin{bmatrix} x^2 & 0 \\ 0 & y^2 \end{bmatrix} = I$$

Next, suppose that the assertion holds for the case when $n = k$. Then, we will show that the assertion also holds for the case when $n = k + 1$. Let P be any real $(k + 1) \times (k + 1)$ matrix that is both upper triangular and orthogonal. Since P is upper triangular, it has the form

$$P = \begin{bmatrix} Q & \alpha \\ 0 & z \end{bmatrix}$$

where Q is $k \times k$ matrix, $\alpha \in \mathbb{R}^k$, and $z \in \mathbb{R}$. Since P is orthogonal, $P^T P = I$. Therefore, we have

$$P^T P = \begin{bmatrix} Q^T Q & Q^T \alpha \\ \alpha^T Q & \|\alpha\|_2^2 + z^2 \end{bmatrix} = I_{k+1} = \begin{bmatrix} I_k & 0 \\ 0 & 1 \end{bmatrix}$$

19

And let us assume our result is true for n equal to k . And we want to show that our assumption also holds for the k is when n equal to $k + 1$.

So, using that if we have a matrix P which is both upper triangular matrix and a orthogonal matrix of size k cross k . Then P has to be a diagonal matrix such that P square equal to I ; That we are assuming that it is true up to the size k cross k . Now, we want to show that this is also true for the size $k + 1$ cross $k + 1$.

So, let P be any real $k + 1$ cross $k + 1$ matrix that is both upper triangular and orthogonal matrix and we write down this P as $Q \alpha \ 0 \ z$; where α is in vector in \mathbb{R}^k and z is just a real value and Q is k cross k matrix.

Now, since P is upper triangular it means that this Q is also an upper triangular matrix. Now, we want to see that this α is going to be a 0 matrix and this P can be written as a diagonal form. So, let us see how it is?

So, since P is orthogonal it means that P transpose P is equal to I . So, let us calculate P transpose P . So, P is given here, $Q \alpha \ 0 \ z$, P transpose is given by Q transpose, α transpose 0 and z here because z is a real. So, as that transpose is same as z . Then we can calculate P transpose P and that is given by Q transpose Q , Q transpose α , α transpose Q and here we have α^2 square plus norm of α^2 square plus z square.

So, now we already know that $P^T P$ is the matrix of size $k+1$. So, let me write it in this following form. Then if you compare this then $Q^T Q$ is nothing but I_k and $Q^T \alpha = 0$ and $\|\alpha\|_2^2 + z^2 = 1$. It means that these relations hold for as equation number 5.

(Refer Slide Time: 07:33)

Thus, we have

$$Q^T Q = I_k, Q^T \alpha = 0 \text{ and } \|\alpha\|_2^2 + z^2 = 1 \quad (5)$$

Since $Q^T Q = I$, it follows that Q is a $k \times k$ orthogonal matrix. Therefore, we see that

$$Q^T \alpha = 0 \Rightarrow Q(Q^T \alpha) = 0 \Rightarrow \alpha = 0$$

Thus, the equation in (5) reduce to

$$Q^T Q = I_k, \alpha = 0 \text{ and } z^2 = 1$$

Therefore, we see that P has the form

$$P = \begin{bmatrix} Q & 0 \\ 0 & \pm 1 \end{bmatrix}$$

where Q is a $k \times k$ orthogonal matrix. Since P is upper triangular, we know that Q is also an upper triangular matrix. Hence, by the induction hypothesis, we know that Q is a $k \times k$ diagonal matrix with $Q^2 = I_k$.

IIT ROORKEE NPTEL ONLINE CERTIFICATION COURSE 20

Now, since $Q^T Q = I$ it follows that Q is $k \times k$ orthogonal matrix. Therefore, we can say that once Q is orthogonal matrix it is nonsingular matrix also. So, then we can apply $Q^{-1} Q^T \alpha = 0$ and we can say that this is this will simply $Q^T \alpha = 0$. So, we can say that this is nothing but $\alpha = 0$.

So, using first second is reduced to $\alpha = 0$. So, second will hold only when, when $\alpha = 0$. Then when $\alpha = 0$ and look at the last one and last one says that your z^2 has to be 1. So, it means that $Q^T Q = I$ identity $\alpha = 0$ and $z^2 = 1$.

So, now look at your P here. So, now, P will reduce to be reduce to $\begin{bmatrix} Q & 0 \\ 0 & \pm 1 \end{bmatrix}$. Now, Q is what? Q is $k \times k$ orthogonal matrix and since P is upper triangular matrix. So, Q has to be upper triangular matrix. So, it means that Q is a matrix of size $k \times k$. And it is both upper triangular matrix and orthogonal matrix. So, it means that by assumption Q has to satisfy this assumption that $Q^2 = I_k$.

(Refer Slide Time: 09:05)

Hence, it follows that P is a diagonal matrix with

$$P^2 = \begin{bmatrix} Q^2 & 0 \\ 0 & 1 \end{bmatrix} = \begin{bmatrix} I_k & 0 \\ 0 & 1 \end{bmatrix} = I_{k+1}$$

This shows that the induction hypothesis also holds for the case when $n = k + 1$. Hence, by induction, the assertion holds for any $n \times n$ real matrix that is both upper triangular and orthogonal. This completes the proof.

FT ROORKEE

NPTEL ONLINE
CERTIFICATION COURSE

21

So, we can say that, P^2 if we calculate P^2 then it is nothing but Q^2 $\begin{bmatrix} 0 & 0 \\ 0 & 1 \end{bmatrix}$ and since Q^2 is equal to I_k . So, we can write this as $\begin{bmatrix} I_k & 0 \\ 0 & 1 \end{bmatrix}$ and this is nothing but your I_{k+1} . So, it means that our P is a diagonal matrix with the P^2 is equal to I_{k+1} .

So, what we have shown here we have shown that our assumption which is which we have assumed is true only for $k \times k$ matrices; Now, also valid for $k+1 \times k+1$. So, that shows that this our assumption is true for all values of n . It means that if we have a matrix of size $n \times n$ and it is both upper triangular and say orthogonal matrix.

Then it is a it is a ortho it is a diagonal matrix; such that P^2 is equal to identity matrix and that proof that completes the proof of this result. And using this result now we want to prove the uniqueness of the QR decomposition of a given matrix. So, let A be a real $n \times n$ nonsingular matrices nonsingular matrix and let A equal to QR ; where Q is orthogonal matrix and R is an upper triangular matrix.

(Refer Slide Time: 10:09)

Theorem 3
Let A be a real nonsingular matrix, and let

$$A = QR \quad (6)$$

where Q is orthogonal and R is upper triangular. If we restrict R to have positive diagonal entries, then Q and R are uniquely determined by (6).

IFT ROORKEE NPTEL ONLINE CERTIFICATION COURSE 22

Now, if we restrict our R to have only positive diagonal entries, then Q and R are uniquely determined by 6; why we are restricting to positive diagonal entries. Because if you look at here we have P is a diagonal entries diagonal matrix such that P square is equal to y . So, it means the diagonal entries are either plus 1 or minus 1.

So, if we restrict it to only plus 1 values; then P is your nothing but identity matrix. So, we are taking this as assumption that R have only positive diagonal entries. Then we want to show that Q and R are uniquely determined by 6.

(Refer Slide Time: 11:04)

Proof. Suppose that

$$A = Q_1 R_1 = Q_2 R_2 \quad (7)$$

where Q_1 and Q_2 are orthogonal, and R_1 and R_2 are upper triangular with positive diagonal entries.
Since A is nonsingular, and

$$R_1 = Q_1^T A \text{ and } R_2 = Q_2^T A$$

It is immediate that R_1 and R_2 are both nonsingular matrices.
Let D be a matrix defined by

$$D = Q_2^T Q_1$$

From (7), we have

$$D = Q_2^T Q_1 = R_2 R_1^{-1} \quad (8)$$

From (8), it is immediate that D is both orthogonal and upper triangular with positive diagonal entries. Hence, we know that D is a diagonal matrix such that $D^2 = I$. Since D has positive diagonal entries, it follows that $D = I$.

IFT ROORKEE NPTEL ONLINE CERTIFICATION COURSE 23

So, let us assume that we have two decomposition of A QR decomposition of A. So, A as $Q_1 R_1$ equal to $Q_2 R_2$.

So, now once we have $Q_1 R_1$ equal to $Q_2 R_2$ and both Q_1 and Q_2 are orthogonal matrix and R_1 and R_2 are upper triangular matrix. Now, we know that A is a nonsingular matrix. So, it means at R_1 and R_2 both are nonsingular matrices. So, I can write R_1 as $Q_1^T A$. Similarly, we can write R_2 as $Q_2^T A$.

And if we use the these two relation $Q_1 R_1$ equal to $Q_2 R_2$. Then we can write this as Q_2 you just multiply by Q_2^T , then $Q_2^T Q_1$ equal to $R_2 R_1^{-1}$. So, that, that D equal to $Q_2^T Q_1$ and then we have the representation D written as $Q_2^T Q_1$ are equal to $R_2 R_1^{-1}$.

So, using this if we define D as $Q_2^T Q_1$. Then it is also equal to $R_2 R_1^{-1}$. Now, since Q_2 and Q_1 are orthogonal. So, it means that D is going to be orthogonal matrix. And since R_1 and R_2 are upper triangular matrices; So, it means that D is also an upper triangular matrix. So, now, D is both orthogonal and upper triangular matrices. And not only this it has only positive diagonal entries. Why? Because in R_2 and R_1 both are having positive diagonal entries; So, $R_2 R_1^{-1}$ will also have positive diagonal entries.

So, now; So, D is what? Now, D is having orthogonal D is orthogonal D is upper triangular and the entries in the diagonals are only positive entries. So, using the previous result, we know that D is a diagonal matrix. And not only it is a diagonal matrix; it is equal to I. Why? Because D^2 is equal to I and since it has only positive diagonal entries it has to be 1 only. So, it means that D has to be identity matrix.

So, if D is equal to identity matrix means $Q_2^T Q_1$ is equal to I and $R_2 R_1^{-1}$ inverse is equal to I. And it means that, Q_2 is equal to Q_1 ; if we use this relation and if you use this and this then this simply says that R_2 is equal to R_1 .

(Refer Slide Time: 13:26)

Hence, (8) becomes

$$I = Q_2^T Q_1 = R_2 R_1^{-1}$$

which shows that

$$Q_2 = Q_1 \text{ and } R_2 = R_1$$

This completes the proof.

FT ROORKEE NPTEL ONLINE CERTIFICATION COURSE 24

So, we have shown that, Q_2 is equal to Q_1 and R_2 equal to R_1 . That proves the uniqueness of QR decomposition. So, it means that once we have this uniqueness result then we are show that whatever method we apply we must have only 1 QR decomposition method.

(Refer Slide Time: 13:54)

Theorem 4
(Householder QR Factorization of a rectangle Matrix) If A is any real $m \times n$ matrix with $m \geq n$, then A can be expressed as

$$A = QR = Q \begin{bmatrix} \tilde{R} \\ 0 \end{bmatrix}$$

where Q is an $m \times m$ orthogonal matrix and \tilde{R} is an $n \times n$ upper triangular matrix. Moreover, the matrix Q can be expressed as a product of Householder matrices. (If A is $m \times n$ matrix with $m \leq n$, then the QR factorization of A is obtained by considering A^T .)

FT ROORKEE NPTEL ONLINE CERTIFICATION COURSE 25

So, now we proceed further and we try to find out the QR factorization Householder, QR factorization of a rectangular matrices. So, here if a is any real m cross n matrix with the m greater than or equal to n, it means that we have less number of columns than the rows

here. Then this A can be expressed as QR ; where Q is the orthogonal matrix of size m cross n and this R is an n cross n upper triangular matrix of this kind.

Moreover the matrix Q can be expressed as a product of Householder matrices. And now suppose we here we started with the m cross n matrix, where m is greater than or equal to n . Then we have this representation, but if we have size of A as m cross n with m is less than or equal to n . Then we can consider this theorem for a A transpose.

So, let us consider this theorem 4 and once we are done with this theorem 4 then we can also deal with the problem of matrix where your m is less than or equal to n . It means a number of rows are strictly less than number of column. So, let us have the proof of this theorem for which is very short. In fact, it is similar to the proof of QR factorization of a square matrix. So, we can make it short.

(Refer Slide Time: 15:30)

Proof.

We construct the Householder matrices H_1, H_2, \dots, H_n successively so that

$$H_n H_{n-1} \dots H_1 A = R = \begin{bmatrix} \tilde{R} \\ 0 \end{bmatrix} \quad (9)$$

where \tilde{R} is an $n \times n$ upper triangular matrix.

Define Q by $Q = H_1 H_2 \dots H_n$. Since each Householder matrix H_i is symmetric, we have

$$Q^T = H_n^T H_{n-1}^T \dots H_1^T = H_n H_{n-1} \dots H_1 \quad (10)$$

From (9) and (10), we have

$$Q^T A = R = \begin{bmatrix} \tilde{R} \\ 0 \end{bmatrix}$$

Since Q is a product of Householder matrices, it is orthogonal. This completes the proof. □

26

So, we construct the Householder matrix H_1 to H_n successively. So, that $H_1 H_{n-1} \dots H_1$ operate when we operate on A , then it is R . Now, here R we have R tilde 0 . Now, if you look at let me write it here, here we have more number of rows. So, here we have m rows. So, here we have A_1 to A_{m-1} and here we have A_1 and here we have $A_{m \times n}$. So, it means that m is greater than n .

So, if you recall when we try to find out this QR decomposition of a given matrix A . What we try to do here? we find out H_1 , such that all the entries in the diagonal terms are simply vanish. And in H_2 . What we do? we look at this term and all these entries we want to make it 0. And up to how many how much how many steps we need to go, here we go up to n step that is we need to go up to find out H_1 up to H_n .

So, it means that here in this proof we need to go to n step. And this Q is going to be $H_1 H_2 \dots H_n$ right. And here if you look at it may happen that some entries are zeros here and it still there are some something nonzero right.

So, here this R have this form R tilde zeroes and R tilde is an n cross n upper triangular matrix. And we can define Q by $H_1 H_2 \dots H_n$. And since each Householder matrix H_i is symmetric, we can say that Q transpose is nothing but Q transpose is given by H_n transpose, H_{n-1} transpose, H_1 transpose.

And since each are symmetric matrix. So, Q transpose is also equal to Q . And Q trans since each H_i is orthogonal matrix. So, Q is also going be orthogonal matrix. So, we can write that Q transpose A as R this is nothing but Q transpose. So, Q transpose into A equal to R . So, we can write A as Q into R is it ok.

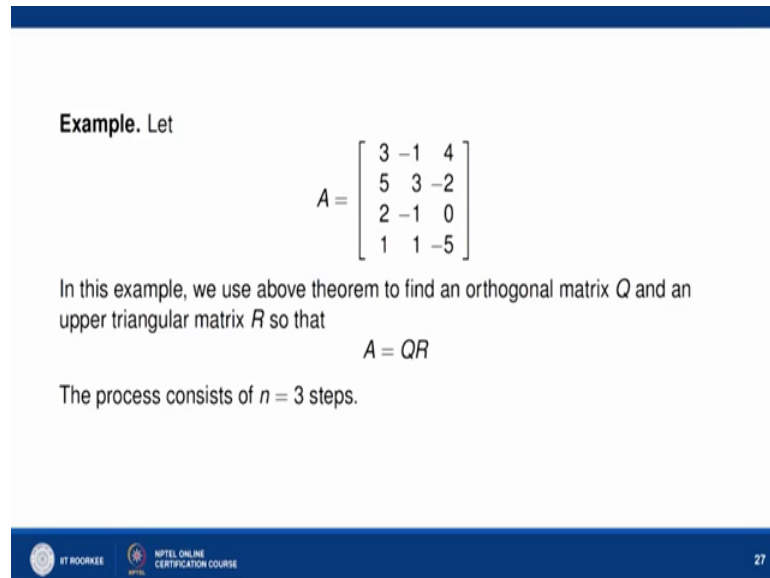

So, this completes the proof. So, it means that here we have nothing more to proof, here we simply follow the proof of the QR decomposition method. The only thing here is that here we can go only up to the n places, because we have only n columns and m is bigger than n . So, it means that it may happen that there are certain bottom rows are simply 0 rows.

So, here we define Q by $H_1 H_2 \dots H_n$. And since each Householder matrix H_i is symmetric, we can find out Q transpose as H_n transpose, H_{n-1} transpose, H_1 transpose. And which is nothing but since H_n transpose is H_n , H_{n-1} transpose is H_{n-1} . So, Q transpose is given by $H_n, H_{n-1} \dots H_1$.

So, using this if you look at the equation number 9; then it is nothing but Q transpose A into R right. And since we know that each one each H_1 to H_n are orthogonal matrix; because it is Householder matrices. So, it is orthogonal matrices also. So, Q is going to be orthogonal matrix.

So, it means that we can write this $Q^T A$ equal to R and since Q is orthogonal matrix. So, we can apply Q here, then I can write A as QR . So, that complete the proof of this theorem. And it is basically this that here we have $m \times n$ matrix and since we have only n columns. So, we can find out only H_1 to H_n . So, we Q we can write it H_1 to H_n is it ok.

(Refer Slide Time: 19:37)

Example. Let

$$A = \begin{bmatrix} 3 & -1 & 4 \\ 5 & 3 & -2 \\ 2 & -1 & 0 \\ 1 & 1 & -5 \end{bmatrix}$$

In this example, we use above theorem to find an orthogonal matrix Q and an upper triangular matrix R so that

$$A = QR$$

The process consists of $n = 3$ steps.

IT ROOKIE NPTEL ONLINE CERTIFICATION COURSE 27

So, now, let us consider one example and try to see how to find out QR decomposition of this example. So, if we have let us find out the QR decomposition of this. Now, here a size is 4×3 . So, we can go up only up to the 3 steps; So, n equal to 3 steps.

(Refer Slide Time: 19:48)

Step 1: Here, we find H_1 so that

$$A_1 = H_1 A = \begin{bmatrix} * & * & * \\ 0 & * & * \\ 0 & * & * \\ 0 & * & * \end{bmatrix}$$

It is easy to see that H_1 is defined by

$$H_1 = I_4 - 2w_1 w_1^T$$

where

$$w_1 = \begin{bmatrix} 0.8603 \\ 0.4653 \\ 0.1861 \\ 0.0931 \end{bmatrix}$$

IFT ROORKEE NPTEL ONLINE CERTIFICATION COURSE 28

So, for that, first we need to find out H_1 . Now, what is the work of H_1 . That if we apply H_1 on A . Then in the first step; we should have in the first column all the entry is below the diagonal term has to be 0. And that we can achieve by using the algorithm. And that we can say that H_1 equal to I_4 minus $2 w_1 w_1^T$. To find out this w_1 we are using the algorithm and we say that w_1 is given by this quantity.

H1=eye(4)-2*w1*w1'
A1=H1*A

```

So, let us see what is going on. So, let me use MATLAB here. So, for that let us define your matrix A as this that is the matrix H A we are using 3 minus 1 4 5 3 minus 2. So, here we are using this 3 minus 1 4 5 3 minus 2. So, that is what we have written here.

(Refer Slide Time: 20:39)

So, once we have A. Then we need to find out H 1 what is doing that it makes the first column as something which is minus 1 0 0 0 that we are going to consider. So, for that first write down what is x 1. So, let me write it x 1 here. So, x 1 is equal to we write the first column of matrix A; that is 3 5 2 1, but x 1 is a not a unit vector. So, we define a unit vector as u 1. So, let us call this as u 1 v u 1 is given by x 1 by norm of x 1. So, u 1 we can find out.

Similarly, for algorithm we need to find out v 1. So, v 1 is minus sign of the first term is here 3; So, minus sign of 3 that is 1. So, it means that v 1 is nothing but minus 1 0 0. So, let me write it here it is minus 1 0 0 0. So, v 1 is going to be this.

Now, u 1 we have v 1 we have and both are unit vector. Then algorithm says that w 1 we can define as u 1 minus v 1 sorry this w 1 is given by u 1 minus v 1 divided by norm of u 1 minus v 1. And if you calculate it is coming out to be 0.8603 0.4653 0.1861. And it is if you look at here we have w 1 as this.

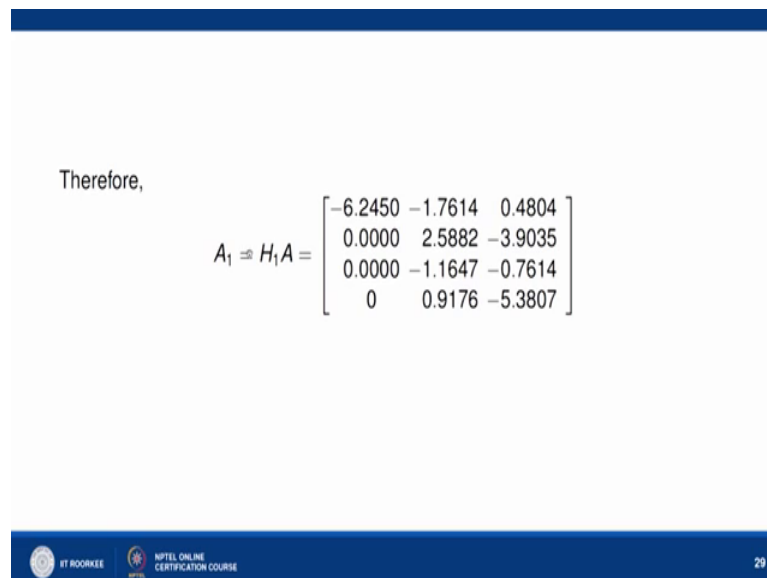

So, here we are using algorithm to find out w 1. And once we have w 1 then H 1 is nothing but I 4 minus 2 omega 1 omega 1 transpose that also I am writing here. So, here

we can write H^{-1} as I_4 this represent the identity matrix of size 4 cross 4 minus 2 into w^{-1} transpose. So, if you calculate sorry it is not $I^{-1} I H^{-1}$ is going to be this.

So, once we have H^{-1} then we can find out A^{-1} as H^{-1} into m and it is coming out to be this form. So, A^{-1} is minus 6.2450 and so on. And if you look at it is matching with this. So, A^{-1} is $H^{-1} A$ which is minus 6 minus 6.2450 it is matching here.

(Refer Slide Time: 23:19)

Therefore,

$$A^{-1} = H^{-1} A = \begin{bmatrix} -6.2450 & -1.7614 & 0.4804 \\ 0.0000 & 2.5882 & -3.9035 \\ 0.0000 & -1.1647 & -0.7614 \\ 0 & 0.9176 & -5.3807 \end{bmatrix}$$

So, we can find out A^{-1} , but here if you look at here we have this entries in first column we have these entries below the diagonal term it is 0, but if you look at the second column it is not 0; these two still are nonzero.

So, we need to go further we need to find out H^{-2} . And to find out H^{-2} we write A^{-2} as H^{-2} into H^{-1} ; where A^{-2} which is given as H^{-2} into A^{-1} ; where H^{-2} is this, A^{-1} is given by this. It must be of this form. Here form is what that in first diagonal the first column entries below the diagonal term it is 0 and in second column entries below the diagonal term it is 0.

(Refer Slide Time: 23:38)

Step 2: Here, we find H_2 so that $A_2 = H_2 A_1$ has the form

$$A_2 = H_2 A_1 = H_2 \begin{bmatrix} -6.2450 & -1.7614 & 0.4804 \\ 0.0000 & 2.5882 & -3.9035 \\ 0.0000 & -1.1647 & -0.7614 \\ 0 & 0.9176 & -5.3807 \end{bmatrix} = \begin{bmatrix} * & * & * \\ 0 & * & * \\ 0 & 0 & * \\ 0 & 0 & * \end{bmatrix}$$

First, we find \hat{H}_2 so that

$$\hat{H}_2 \begin{bmatrix} 2.5882 \\ -1.1647 \\ 0.9176 \end{bmatrix} = \begin{bmatrix} * \\ 0 \\ 0 \end{bmatrix}$$

It is easy to show that

$$\hat{H}_2 = I_3 - 2\hat{w}_2\hat{w}_2^T$$

where

$$\hat{w}_2 = \begin{bmatrix} 0.9664 \\ -0.2020 \\ 0.1592 \end{bmatrix}$$

30

So, we need to find out H_2 , such that it makes these entries this thing to this form right. So, here H_2 hat will first to define H_2 we need to define first of all what is H_2 hat? So, H_2 hat will give you what? look at the second column. This diagonal entries is 2.5882 let me write it here 2.5882 minus 1. So, here we have considered this. And we want to write this into this form.

Now, here what is this nonzero quantity. Since this entry is plus 1. So, this entry is going to be minus 1. So, minus 1 0 0; So, we need to find out H_2 hat which map this 2 minus 1 0 0. So, now, we again apply our algorithm and we can write H_2 hat as I_3 minus 2 ω_2 hat ω_2 hat transpose.

Now, how to find out this ω_2 ω_2 hat. Then we use algorithm this is our x, this is your y. So, now, to find out x we can define u_2 that is x 2 divided by norm of x 2 and v_2 that is minus 1 0 0. And your w_2 is going to be u_2 minus v_2 divided by norm of u_2 minus v_2 . And we can write this as W_2 hat. And here I am not doing this calculation you can do this. So, again W_2 hat is what? u_2 that is this divided by norm of this minus v_2 that is minus 1 0 0 divided by norm of u_2 minus v_2 . So, W_2 hat is given to us.

(Refer Slide Time: 25:49)

Thus, H_2 is defined as

$$H_2 = \begin{bmatrix} I_1 & 0 \\ 0 & \hat{H}_2 \end{bmatrix}$$

i.e. $H_2 = I_4 - 2w_2w_2^T$, where

$$w_2 = \begin{bmatrix} 0 \\ \hat{w}_2 \end{bmatrix} \in \mathbb{R}^4$$

Therefore, we have

$$A_2 = H_2 A_1 = \begin{bmatrix} -6.2450 & -1.7614 & 0.4804 \\ 0.0000 & 2.99829 & 4.7451 \\ 0.0000 & 0.0000 & -2.5695 \\ 0.0000 & 0.0000 & -3.9561 \end{bmatrix}$$

Now, once we have \hat{w}_2 ; we can define H_2 that is $I \ 1 \ 0 \ 0 \ H_2 \ \hat{H}_2$ and we already know that H_2 is given by $I_4 - 2\omega_2\omega_2^T$ where ω_2 is this. So, it means that H_2 is going to be an Householder matrix here. Then if we operate H_2 on A_1 then A_2 will be of this form.

So, here if you look at here in the last column here let us this entry below the diagonal term is 0, here this is upper triangular matrix. So, here we can say that diagonal term is this minus 2.5695. So, here we have to find out another Householder matrix say H_3 ; which make these two term as nonzero term into and zero term.

(Refer Slide Time: 26:48)

Step 3: Here, we find H_3 so that $A_3 = H_3 A_2$ has the form

$$A_3 = H_3 A_2 = H_3 \begin{bmatrix} -6.2450 & -1.7614 & 0.4804 \\ 0.0000 & -2.9829 & 4.7451 \\ 0.0000 & 0.0000 & -2.5695 \\ 0.0000 & 0.0000 & -3.9561 \end{bmatrix} = \begin{bmatrix} * & * & * \\ 0 & * & * \\ 0 & 0 & * \\ 0 & 0 & 0 \end{bmatrix}$$

First, we find \hat{H}_3 so that

$$\hat{H}_3 \begin{bmatrix} -2.5695 \\ -3.9561 \end{bmatrix} = \begin{bmatrix} * \\ 0 \end{bmatrix}$$

It is easy to see that $\hat{H}_3 = I_2 - 2\hat{w}_3\hat{w}_3^T$, where

$$\hat{w}_3 = \begin{bmatrix} -0.8788 \\ -0.4771 \end{bmatrix}$$

Thus H_3 is defined by

$$H_3 = \begin{bmatrix} I_2 & 0 \\ 0 & \hat{H}_3 \end{bmatrix}$$

So, again we go to find out H_3 . So, H_3 we will find out such that A_3 which is given as H_3 into A_2 have the following form. A_3 is $H_3 A_2$ equal to $H_3 A_2$ is given by this. And this has the form that the entries in the third column below the diagonal term, is going to be 0.

So, how do you find out this H_3 hat look at the factor of H_3 hat. H_3 hat make these two term this two term into something nonzero into zero. Now, look at the something nonzero, here the sign of this is minus 1. So, it is going to be 1 0. So, H_3 hat will map this two 1 0.

Now, again since here we can use the algorithm. So, here it is some x_4 we can call this x_3 here; let us say x_3 here. So, it is a non unit vector. So, we define u_3 as this x_3 divided by norm of x_3 , v_3 as 1 0 and w_3 hat as u_3 minus v_3 divided by norm of u_3 minus v_3 . So, that gives you w_3 hat. Once we have W_3 hat your H_3 hat is given by I_2 minus 2 ω_3 hat ω_3 hat transpose.

(Refer Slide Time: 28:03)

i.e. $H_3 = I_4 - 2w_3w_3^T$, where

$$w_3 = \begin{bmatrix} 0 \\ \hat{w}_3 \end{bmatrix} \in \mathbb{R}^4$$

Therefore, we have

$$R = A_3 = H_3 A_2 = \begin{bmatrix} -6.2450 & -1.7614 & 0.4804 \\ 0.0000 & -2.9829 & 4.7451 \\ 0.0000 & 0.0000 & 4.7174 \\ 0.0000 & 0.0000 & 0.0000 \end{bmatrix}$$

and

$$Q = H_1 H_2 H_3 = \begin{bmatrix} -0.4804 & 0.6189 & 0.2743 & 0.5576 \\ -0.8006 & -0.5330 & 0.1937 & -0.1935 \\ -0.3203 & 0.5244 & -0.4948 & -0.6145 \\ -0.1601 & -0.2407 & -0.8015 & 0.5235 \end{bmatrix}$$

IT ROORKEE NPTEL ONLINE CERTIFICATION COURSE 33

And then we can define $W_3 \omega_3$ as 0 ω_3 hat. And if we calculate I_4 minus 2 $\omega_3 \omega_3$ hat then it is coming out to be H_3 ; where H_3 is of this form block diagonal matrix I_2 0 0 H_3 ha. So, it means that H_3 is since H_3 is written as I_4 minus 2 $\omega_3 \omega_3$ hat and ω_3 is of unit vector because ω_3 hat is going to be unit vector. So, it means that H_3 is a Householder matrix.

Now, if we apply H_3 on A_2 , then you look at that here it will be an upper triangular matrix form. And once we have if you look at the diagonal entries, in diagonal entries any entries below the diagonal terms is all 0. So, it is achieved here. So, it means that here we stop and we call this matrix as R . R is nothing but A_3 . So, A_3 is $H_3 A_2$ and A_2 is $H_2 A_1$ and A_1 is $H_1 A$. So, we can write R as and this thing and Q is given by $H_1 H_2 H_3$ and it is like this here.

So, here we have achieved QR decomposition of a non square matrix that is a rectangular matrix. And if we have a rectangular matrix whose number of rows is less than number of columns, then we try to find out the QR decomposition for the transpose of that matrix. And again we can find out this Q and R using your MATLAB command; $QR = \text{qr}(A)$. So, that will give you your R that is minus 6.4250 minus 1 this is R we have achieved here. And we already know that it is unique. So, uniqueness is also followed from this is it ok.

So, here I will stop here our lecture. So, in this lecture what we have seen we have seen QR decomposition is a unique one. And we can extend this result to non square matrices. So, it means that QR decomposition of a non square matrix that is the rectangular matrix also we can find out with the help of the proof of the QR decomposition of a square matrix. So, in that we have done in this lecture.

So, in next lecture we will try to see some application of QR decomposition. So, here that is we stop and

Thank you for listening us, thank you.
