Lecture – 25
Evaluation of Real Integrals Using Residues - V

Hello friends welcome to my last lecture on evaluation of real integrals using residues. So in this lecture again we are going to consider 2 real integrals which need different technique for evaluation and at different contour also in one case.

(Refer Slide Time: 00:50)

Example 1
 Show that
$$\int_0^{\infty} \frac{\cosh ax}{\cosh x} dx = \frac{\pi}{2 \cos \frac{\pi a}{2}}, \text{ where } |a| < 1.$$

Figure : Fig.1

Now let us consider for example the real integral 0 to infinity cosh hyperbolic ax/cosh hyperbolic x dx. We are going to show that it is value is pi/2 cosh pi a/2 where mod of a is <1. So in this example we will use this contour, where we take the rectangle with vertices at -r + r, r + i pi and -r + i pi. So we are moving along this rectangle in the counter clockwise direction and we will see that the corresponding contour integral which we consider here that has a simple pole at z = i pi/2 which lies in the upper half plane okay.

So that is inside the rectangle and therefore we can make use of the residue theorem to evaluate the value of the integral around this close contour. So let us consider this close contour. So consider the contour integral, so we are going to consider the contour integral, integral/C for cosh hyperbolic ax we write e to the power az and for the denominator cosh hyperbolic x we write cosh hyperbolic z.

(Refer Slide Time: 02:08)

Solution: Consider the contour integral $\int_C \frac{e^{az}}{\cosh z} dz$ where C is the rectangle having vertices at $-R, R, R + \pi i, -R + \pi i$

$f(z) = \frac{e^{az}}{\cosh z}$ has simple poles at the points where

$$\cosh z = 0 \Rightarrow z = -\left(n + \frac{1}{2}\right)\pi i,$$

out of which only the simple pole at $\frac{\pi i}{2}$ lies inside C .

$\text{Res}\left(\frac{e^{az}}{\cosh z}\right)_{z=\frac{\pi i}{2}} = \frac{e^{a\frac{\pi i}{2}}}{\sinh\left(\frac{\pi i}{2}\right)} = \frac{e^{i\frac{\pi a}{2}}}{i} = -i e^{i\frac{\pi a}{2}}$

Handwritten notes:
 Let $\phi(z) = \cosh z$
 $\phi'(z) = \sinh z$
 $\Rightarrow \cosh z = 0$
 $\cosh z = \cosh z$
 Hence $\cosh z = 0$
 $\Rightarrow iz = (2n+1)\frac{\pi}{2}$
 $n = 0, \pm 1, \pm 2, \dots$
 $\Rightarrow z = (2n+1)\frac{\pi}{2} i$
 $\phi(z) = \sinh z = -\left(n + \frac{1}{2}\right)\pi i$
 $n = 0, \pm 1, \pm 2, \dots$
 $\neq 0$ at $z = -\left(n + \frac{1}{2}\right)\pi i$
 $-1 = i \sinh\left(\frac{\pi}{2}\right)$

So integral over C is $\int_C \frac{e^{az}}{\cosh z} dz$, where C is the rectangle having vertices at $-R, R, R + \pi i$ and $-R + \pi i$. Now $f(z) = \frac{e^{az}}{\cosh z}$ has poles where the denominator, $\cosh z = 0$. So let us say let $iz = \cosh z$, then we notice that $\cosh iz = 0$ means $\cosh z = 0$ and let us recall that $\cosh iz = \cosh z$.

So then $\cosh z = 0$ implies $\cosh iz = 0$, which means that $iz = 2n + 1 * \pi/2$ where $n = 0 +/ - 1 +/ - 2$ and so on and so $z = 2n + 1 * \pi/2 * 1/i$, $1/i$ means $-i$ okay. So we can write it as $-n + 1/2 * \pi i$ okay, this is $-n + 1/2 * \pi i$ okay and n takes values $0 + -1 + -2$ and so on, okay. Now out of these poles okay, now let us see one more thing that $\phi'(z) = \sinh z$ is $\cosh z$, hyperbolic z .

So $\phi'(z)$ is $\sinh z$ and $\sinh z$ is not 0, wherever $\cosh z$ is 0 okay. So $\sinh z$ is not 0 at $z = -n + 1/2 * \pi i$ okay. So at $z = -n + 1/2 * \pi i$, this $\phi'(z)$, this $f(z)$ has simple poles okay. So $f(z) = \frac{e^{az}}{\cosh z}$ has simple poles at these points okay. Now out of the points $z = -n + 1/2 \pi i$ where $n = 0 +/ - 1 +/ - 2$ and so on okay.

Only the pole $\pi i/2$ okay, only the pole $\pi i/2$ lies inside the rectangle bounded by $-R, R, R + \pi i$ and $-R + \pi i$. So we will need to consider the residue only at $z = \pi i/2$. So let us find the residue of $\frac{e^{az}}{\cosh z}$ at $z = \pi i/2$. Now here it is easier if we differentiate the denominator of $\frac{e^{az}}{\cosh z}$ and put $z = \pi i/2$. So this residue of e

to the power az/\cosh hyperbolic z at $z = i\pi/2$ is same as $is = e$ to the power $az/$ the derivate of \cosh hyperbolic z that is \sin hyperbolic z and we evaluate it at $z = i\pi/2$.

So this is e to the power $a i\pi/2$ okay and \sin hyperbolic $i\pi/2$, okay. Now let us recall that $\sin iz = i \sin$ hyperbolic z . So when you put z as $i\pi/2$ what we get? $\sin i * i\pi/2 = i \sin$ hyperbolic $i\pi/2$. This \sin is i square $\pi/2$, i square is -1 , so $\sin -\pi/2$ which is $-1 = i$ times \sin hyperbolic $i\pi/2$ okay and $-1/i$ is i okay. So \sin hyperbolic $i\pi/2$ is i so this is e to the power $i a\pi/2 / i$ okay.

\sin hyperbolic $i\pi/2 = -1/i$, $-1/i$ is i , $1/i$ is $-i$ so we get $-i e$ to the power $i a\pi/2$ okay. So we get this $-i e$ to the power $ai\pi/2$ as the residue of e to the power az/\cosh hyperbolic z , at $z = i\pi/2$.

(Refer Slide Time: 07:28)

Now,

$$\int_C f(z) dz = \int_{-R}^R f(x) dx + \int_0^\pi \frac{e^{a(R+iy)}}{\cosh(R+iy)} i dy + \int_R^{-R} \frac{e^{a(x+i\pi)}}{\cosh(x+i\pi)} dx + \int_\pi^0 \frac{e^{a(-R+iy)}}{\cosh(-R+iy)} i dy = 2\pi e^{\frac{a\pi i}{2}} \text{ by residue theorem.}$$

$z = R+iy$
 $dz = i dy$

Let us show that the second integral tends to zero as $R \rightarrow \infty$.

$$\left| \cosh(R+iy) \right| = \left| \frac{e^{R+iy} + e^{-R-iy}}{2} \right| \geq \frac{1}{2} \left\{ |e^{R+iy}| - |e^{-R-iy}| \right\}$$

$$= \frac{1}{2} (e^R - e^{-R}) \geq \frac{1}{4} e^R \rightarrow \text{(it is true if } e^{2R} \geq 2)$$

Let $e^x = x$
 $\frac{1}{x} (x - \frac{1}{x}) > \frac{1}{x}$
 $\frac{x-1}{x} > \frac{1}{x}$
 $2x^2 > 2x$
 $x^2 > 2$
 $e^{2x} > 2$

Now we write the integral around the contour C . So integral around the contour C is integral from $-r$ to r along the real axis that means we replace z/x . So integral along $-r$ to r where z is replaced by x and we get this integral $\int_{-r}^r f(x) dx$, now going from r to $r + i\pi$. So that means that when we go from r to $r + i\pi$ x is constant. So z will be $r + iy$, any point z you take on this segment r to $r + i\pi$, z will be $r + iy$ where y varies from 0 to π okay.

So we will put that here, e to the power az upon \cosh hyperbolic z that is e to the power a times $r + iy/\cosh$ hyperbolic $r + iy$ and when z is $r + iy$ we have $dz = i dy$. So we put $i dy$ here and y varies from 0 to π . Now when we move along this segment from $r + i\pi$ to $-r + i\pi$

then you can see that now we will have $z =$ because now y is constant, x varies okay. So $x + i\pi$ okay, $x + i\pi$ is $= \pi$ along this line.

So $x + i\pi$ and x varies from $r^2 - 2$ and dz will be $= dx$ okay. So let us put this here in the third case, so x varies from r to $-r$, e to the power a times $x + i\pi / \cosh$ hyperbolic $x + i\pi$ dx and then we move along the segment $-r + i\pi$ to $-r$. So when we move along $-r + i\pi$ to $-r$ x is now $-r$. So $z = -r + iy$ okay for this, $z = -x + r + iy$ $dz = -dy$ and y varies from π to 0 . So here you can see $\int_{\pi}^0 e^{-r+iy} \cosh$ hyperbolic $-r+iy$ dz becomes idy and then righthand side is by residue theorem $2\pi i$ * okay.

So we multiply $2\pi i$ to the residue and $2\pi i * -i$ is $-2\pi i$ square that is 2π . So we get 2π * e to the power a $\pi/2$ okay. Now let us show that the second integral on the right side this one okay. This integral tends to 0 as r goes to infinity. So mod of first let us evaluate, let us take lower bound rather. Lower bound for \cosh hyperbolic $r + iy$. So mod of \cosh hyperbolic $r + iy$ is mod of e to the power $r + iy$ + e to the power $-r - iy$ / 2 and mod of z_1 to z_2 is $\geq \text{mod } z_1 - \text{mod } z_2$.

So we have mod of this + this $\geq 1/2 e$ to the power mod of $r + iy$ - mod of e to the power $-r - iy$. Now mod of e to the power iy is 1 . So we have this as e to the power r okay and this is e to the power $-r$. Now $1/2 e$ to the power r - e to the power $-r$ is $\geq 1/4$ times e to the power r if e to the power $2r$ is \geq this we can easily see. Let us say let e to the power r be $=x$ okay.

Then what we want? $1/2 x - 1/x$, this is e to the power $-r$ is $1/x$, we wanted to be $\geq 1/4 x$ okay. So what we want this is $x^2 - 1/x \geq 1/2 x$. This means we want $2x^2 - 2$ to be $\geq x^2$ and this means x^2 should be ≥ 2 , so e to the power $2r$ must be ≥ 2 , or e to the power r must be $\geq \sqrt{2}$ okay. It is not always true okay, but here we are taking r to go to infinity okay.

Here we want r to go to infinity so this inequality is valid okay. So $1/4 e$ to the power r is the lower bound for \cosh hyperbolic $r+iy$ and then we have.

(Refer Slide Time: 12:24)

We have

$$\left| \int_0^\pi \frac{e^{a(R+iy)}}{\cosh(R+iy)} idy \right| \leq \int_0^\pi \frac{e^{aR}}{\frac{1}{4}e^R} d\theta \quad \left| e^{a(R+iy)} \right| = e^{aR}$$

$$= 4\pi e^{(a-1)R} \rightarrow 0, \text{ as } R \rightarrow \infty \text{ since } |a| < 1.$$

Similarly, let us show that the fourth integral

$$\int_\pi^0 \frac{e^{a(-R+iy)}}{\cosh(-R+iy)} idy \rightarrow 0, \text{ as } R \rightarrow \infty.$$

$$\left| \cosh(-R+iy) \right| = \left| \frac{e^{-R+iy} + e^{-(-R+iy)}}{2} \right| = \left| \frac{e^{-R+iy} + e^{R-iy}}{2} \right| \geq \frac{|e^{R-iy}| - |e^{-R+iy}|}{2}$$

$$\left| \int_\pi^0 \frac{e^{a(-R+iy)} dy}{\cosh(-R+iy)} \right| \leq \int_0^\pi \frac{e^{-aR}}{\frac{1}{4}e^R} dy = 4\pi e^{-(a+1)R} \rightarrow 0, \text{ as } R \rightarrow \infty \text{ because } |a| < 1$$

So we can now evaluate this integral, mod of integral 0 to pi e to the power times r + iy/cosh hyperbolic r + iy idy is now <= now mod of e to the power a r + iy as we have seen earlier also, this is e to the power ar because mod of e to the power ai y = 1. So e to the power ar for this and this is >= 1/4 e to the power r. So 1 up on cosh hyperbolic r + iy is <= 1 upon 1/4 e to the power r.

So this is now = 4 pi e to the power a-1 * r, but you see mod of a is < 1. So e to the power a-1 * r okay. This is always e to the power a-1, a-1*r is always negative and therefore this goes to 0 as r goes to infinity. Similarly, we can show that this fourth integral goes to 0 as r goes to infinity, but we do, let us consider first lower bound for cosh hyperbolic - r + iy. So mod of cosh hyperbolic - r + iy let us find.

So this is = mod of e to the power - r + iy + e to the power - of - r + iy/2 and this is = mod of e to the power - r + iy + e to the power r - iy, okay this is >= mod of this, let us first take this, mod of this - mod of that. So mod of e to the power r - iy - mod of e to the power - r + iy okay. Mod of e to the power, this is e to the power r * e to the power -iy mod of that is 1. So this is = e to the power r - e to the power - r/2.

Now as we have seen here e to the power r - e to the power - r/2 is >= 1/4 e to the power r. So here also it is >= 1/4 e to the power r provided if e to the power 2r is >= 2 okay. So this is true because r is going to infinity. Now mod of, okay so mod of pi to 0, e to the power a times - r + iy * dy/cosh hyperbolic - r + iy, this is <= integral pi to 0 become 0 to pi, because mod is there.

So we have e to the power $-ar/4$ e to the power r dy okay. So dy we have, so this is = 4 times $\pi * e$ to the power $-a - 1 * r$ okay. Again mod of $a < 1$ okay. So this goes to 0 as r goes to infinity because mod of a is < 1 okay. So this is how we show that this integral okay and this integral, they go to 0 as r goes to infinity. Now as r goes to infinity what we have integral/-infinity to infinity $fx dx +$ integral/infinity to $-$ infinity. This $dx =$ the residue, that is we found that to be this one.

(Refer Slide Time: 16:21)

Hence we obtain

$$\lim_{R \rightarrow \infty} \left\{ \int_{-R}^R \frac{e^{ax}}{\cosh x} dx + e^{a\pi i} \int_{-R}^R \frac{e^{ax}}{\cosh x} dx \right\}$$

$= 2\pi e^{\frac{a\pi i}{2}}$, since $\cosh(x + \pi i) = -\cosh x$

$$\int_{-\infty}^{\infty} \frac{e^{ax}}{\cosh x} dx = \frac{\pi}{\cos(\frac{\pi a}{2})}$$

Hence

$$\int_0^{\infty} \frac{\cosh ax}{\cosh x} dx = \frac{\pi}{2 \cos(\frac{\pi a}{2})}$$

Handwritten notes include: $\int_{-\infty}^{\infty} \frac{e^{ax}}{\cosh x} dx = \frac{\pi}{\cos(\frac{\pi a}{2})}$, $\cosh z = \frac{e^z + e^{-z}}{2}$, $\cosh(x + \pi i) = \frac{e^{x+\pi i} + e^{-x-\pi i}}{2} = \frac{e^x + e^{-x}}{2} = -\cosh x$, $\int_0^{\infty} \frac{e^{ax}}{\cosh x} dx = \frac{\pi}{2 \cos(\frac{\pi a}{2})}$, $\int_{-\infty}^{\infty} \frac{e^{ax}}{\cosh(x+i\pi)} dx = 2\pi e^{a\pi i/2}$, $\int_{-\infty}^{\infty} \frac{e^{ax}}{\cosh x} dx = \frac{2\pi e^{a\pi i/2}}{1 + e^{a\pi i}}$

So integral limit r tends to infinity $-r$ to r , e to the power ax \cosh hyperbolic $dx +$ integral over okay let us see how we get this. Okay here you can see when r goes to infinity this equation gives you integral over C , $\int_C f(z) dz$ we found $2\pi i$ times this and $2\pi i - 2\pi i$ square means $2\pi i$ times e to the power $ai \pi/2$ okay. So $2\pi i$ e to the power $ai \pi/2 = -$ infinity to infinity $fx dx +$ integral over infinity to $-$ infinity okay, e to the power $ax * e$ to the power $ai \pi$, dx/\cosh hyperbolic $x + i \pi$.

So this gives you this equation, limit R tends to infinity this equation we get. Here e to the power $ai \pi$ integral $-R$ to R , e to the power ax \cosh hyperbolic dx , now can be changed to integral over $-$ infinity to $+$ infinity because \cosh hyperbolic $x + i \pi = -\cosh$ hyperbolic x okay. So this is here limit R tends to infinity integral/ $-R$ to R e to the power $ax dx/\cosh$ hyperbolic $x + e$ to the power $ai \pi$ integral/ $-R$ to R , e to the power ax/\cosh hyperbolic $x + i \pi$ and \cosh hyperbolic $x + i \pi = -\cosh$ hyperbolic x , this we can see.

Cosh hyperbolic $z = e$ to the power $z + e$ to the power $-z/2$ okay, so cosh hyperbolic $ix + i\pi = e$ to the power $x + i\pi + e$ to the power $-x - i\pi/2$ and e to the power $i\pi$ is -1 . So e to the power x , e to the power $-i\pi$ is also -1 . So e to the power $-x/2$, this is $-\cosh$ hyperbolic x , okay. So this is $-\cosh$ hyperbolic x , so this will become what, integral/- infinity to infinity e to the power ax , dx/\cosh hyperbolic $x + \text{integral/- infinity to infinity}$ okay.

Integral/infinity to $-\infty$, it will be like this, this will be or this is integral/- infinity to infinity, e to the power ax dx upon cosh hyperbolic $x + e$ to the power $ai\pi$ integral/infinity to $-\infty$. This will be integral/infinity to $-\infty$ e to the power ax dx upon cosh hyperbolic $x + i\pi$ okay this is the $= 2\pi$ e to the power $a\pi/2$ okay. Now because cosh hyperbolic $x + i\pi = -\cosh$ hyperbolic x .

We can write it as integral/-infinity to infinity e to the power ax , dx/\cosh hyperbolic $x = 2\pi$ e to the power $ai\pi/2 + e$ raise to the power $e\pi i$ okay, this is what we get. So now we will go, this will break into 2 parts, integral/-infinity to 0, e to the power ax dx/\cosh hyperbolic $x + \text{integral/0 to infinity}$ e to the power ax/\cosh hyperbolic x dx okay $= 2\pi$, e to the power $ai\pi/2$ we can divide in the numerator and denominator we get e to the power $-ai\pi/2 + e$ to the power $ai\pi/2$ okay.

So this is $2\pi/e$ to the power $i\theta + e$ to the power $-i\theta$ is $2\cosh$ θ , $2\cosh$ $a\pi/2$, okay, so this we can cancel. We get π/\cosh $a\pi/2$ okay. Now here what we do on the left side, replace x by $-x$ in this integral okay, then what we will get, e to the power $-ax$ here, this cosh hyperbolic $-x$ is cosh hyperbolic x and dx will become $-dx$, so the limits of integration will change to 0 to infinity.

So we will get 0 to infinity e to the power $-ax$ dx upon cosh hyperbolic x when we replace x by $-x$ in the first integral $+ \text{integral 0 to infinity}$ e to the power ax dx/\cosh hyperbolic $x = \pi/\cosh$ $a\pi/2$, okay so this is left hand side is what, we get left hand side as 0 to infinity e to the power $ax + e$ to the power $-ax/\cosh$ hyperbolic x , e to the power $ax + e$ to the power $-ax$ is twice cosh hyperbolic ax/\cosh hyperbolic x $dx = \pi/\cosh$ $a\pi/2$ okay.

So we get the value integral 0 to infinity cosh hyperbolic ax/\cosh hyperbolic x , $dx = \pi/2$ times okay this 2 we can bring here. So $\pi/2$ times cosh $\pi/2$, so this is how we get the value of the integral using residue calculus.

(Refer Slide Time: 22:50)

Example 2

Show that

$$\int_0^{\infty} \frac{\ln(x^2 + 1)}{x^2 + 1} dx = \pi \ln 2.$$

Solution: Consider

$$\int_C \frac{\ln(z+i)}{z^2+1} dz$$

around the contour C consisting of the real axis from $-R$ to R and the semi-circle Γ of radius R . Let

$$f(z) = \frac{\ln(z+i)}{z^2+1},$$

then $f(z)$ has a simple pole at $z = i$ inside C .

Okay so let us now consider another real integral which is integral from 0 to infinity of $\frac{\ln(x^2 + 1)}{x^2 + 1} dx$ and we will show that its value is $\pi \ln 2$. Okay. Now let us consider the corresponding contour integral here we shall take as integral over C , $\frac{\ln(z+i)}{z^2+1}$, for $\frac{\ln(x^2 + 1)}{x^2 + 1}$ we shall be writing $\frac{\ln(z+i)}{z^2+1}$ when we have $x^2 + 1$ we write again $x^2 + 1$, there is change in the numerator.

In the numerator we simply do not replace x, y, z , we rather consider $\ln(z+i)$. So integral over C of $\frac{\ln(z+i)}{z^2+1} dz$ around the contour C consisting of the real axis from $-R$ to R . So that contour are same as we have been considering earlier. So $-R$ to R and this is 0 origin as semicircle Γ we are moving anti clockwise and then the function $f(z)$ which is $\frac{\ln(z+i)}{z^2+1}$ it has a simple pole okay.

It has actually poles, simple poles at $z = \pm i$, this gives you $z = \pm i$, but out of these 2 simple poles only 1 pole at $z = i$ lies inside C okay. So we will consider the residue of $f(z)$ at $z = i$ only. So let us find the residue.

(Refer Slide Time: 24:18)

$$\text{Res}_{z=i} f(z) = \frac{\ln 2i}{2i}$$

$$\begin{aligned} \text{Res}_{z=i} f(z) &= \text{Res}_{z=i} \frac{\ln(z+i)}{z^2+1} \\ &= \left[\frac{\ln(z+i)}{2z} \right]_{z=i} \\ &= \frac{\ln 2i}{2i} \end{aligned}$$

Hence by residue theorem

$$\int_C \frac{\ln(z+i)}{z^2+1} dz = \pi \left\{ \ln 2 + \frac{i\pi}{2} \right\}, \quad (\text{using principal value of logarithm})$$

Now,

$$\int_{-R}^R \frac{\ln(x+i)}{x^2+1} dx + \int_{\Gamma} \frac{\ln(z+i)}{z^2+1} dz = \pi \ln 2 + \frac{i\pi^2}{2}$$

$$\int_C \frac{\ln(z+i) dz}{z^2+1} = 2\pi i \text{Res}_{z=i} f(z) = 2\pi i \left(\ln 2 + \frac{i\pi}{2} \right) = 2\pi \left(\ln 2 + \frac{i\pi}{2} \right)$$

$$\begin{aligned} \ln 2i &= \ln|2i| + i \arg(2i) \\ &= \ln 2 + i \frac{\pi}{2} \end{aligned}$$

Residue of fz at $z = i$ okay, so residue of fz at $z = i$ let us find. So fz is $\ln z + i/z^2 + 1$. So we can differentiate the denominator, the denominator derivative is $2z \ln z + i$ and then you put $z = i$. So what we get $\ln 2i/2i$ okay, because for z we are writing i , so $\ln 2i/2i$, now $\ln 2i = \ln \text{mod of } 2i + i \text{ times argument of } 2i$ okay and you see $2i$ is here, okay, $2i$ is the point $0, 2$ on y axis okay.

So argument of $2i$ is $\pi/2$ okay, this is $\pi/2$, so we have $\ln \text{mod of } 2i$, this is $\text{mod of } 2i$ is 2 , so $\ln 2 + i \text{ times } \pi/2$ okay. So we have here, now what we have $\int_C \ln z + i/z^2 + 1 dz$ is $2\pi i$ times this is $= \int_C \ln z + i dz/z^2 + 1 = 2\pi i$ times the residue of fz and $z = i$, so this is $2\pi i$ times $\ln 2 + i \pi/2$, okay, $\ln 2 + i \pi/2 / 2i$ okay, so divided by $2i$. So we get this.

So we get π times $\ln 2 + i \pi/2$, okay, so we get this, we are using here principle value of the algorithm. Now we can write the \int_C okay, $\int_C fz dz = \int_{-R}^R fx dx$ because we are moving along the x axis $+ \int_{\Gamma} fz dz$. Let us take this R to be so large that the pole at $z = i$ lies inside the contour okay. So by residue theorem we will have $-R$ to R integral over $-R$ to R $\ln x + i$.

We are moving along x axis, so $\int_{-R}^R \ln x + i/x^2 + 1 dx + \int_{\Gamma} \ln z + i/z^2 + 1 dz = \pi \ln 2 + i \pi^2/2$.

(Refer Slide Time: 27:17)

or

$$\int_{-R}^0 \frac{\ln(x+i)}{x^2+1} dx + \int_0^R \frac{\ln(x+i)}{x^2+1} dx + \int_{\Gamma} \frac{\ln(z+i)}{z^2+1} dz = \pi \ln 2 + \frac{i\pi^2}{2}$$

or

$$\int_0^R \frac{\ln(i-x)}{x^2+1} dx + \int_0^R \frac{\ln(x+i)}{x^2+1} dx + \int_{\Gamma} \frac{\ln(z+i)}{z^2+1} dz = \pi \ln 2 + \frac{i\pi^2}{2}$$

Hence

$$\int_0^R \frac{\ln(1+x^2)}{x^2+1} dx + \int_0^R \frac{i\pi}{x^2+1} dx + \int_{\Gamma} \frac{\ln(z+i)}{z^2+1} dz = \pi \ln 2 + \frac{i\pi^2}{2}$$

$\ln(-1) = \ln e^{i\pi} = i\pi$
 $\int_0^{\infty} \frac{\ln(1+x^2)}{x^2+1} dx + i \int_0^{\infty} \frac{\pi}{x^2+1} dx = i\pi \ln 2 + \frac{i\pi^2}{2}$
 $\ln(i-x) + \ln(i+x) = \ln(i-x)(i+x) = \ln(-1-x^2) = \ln(-1) + \ln(1+x^2) = i\pi + \ln(1+x^2)$

Okay now this integral when r goes to infinity. When r goes to infinity we shall show that integral along gamma goes to 0 and this integral becomes integral/-infinity to infinity $\ln x + i/x^2 + 1 dx$, we will break into 2 parts. So integral/-infinity to 0 and then integral/0 to infinity. So integral/-r to 0 $\ln x + i/x^2 + 1 dx + \int_0^r \ln x + i/x^2 + 1 dx + \int_{\Gamma} \ln z + i/z^2 + 1 dz = \pi \ln 2 + i \pi^2/2$.

And this we can write as integral/, now here replacing x by -x, when you replace x by -x, what you get? $\ln i - x/x^2 + 1 dx$ becomes $- dx$, so the limits change to 0 to R. So $\int_0^R \ln i - x/x^2 + 1 + \int_0^R \ln x + i/x^2 + 1 dx + \int_{\Gamma} \ln z + i/z^2 + 1 dz = \pi \ln 2 + i \pi^2/2$ and then what we do, we can combine this integral and this integral okay. So noting that $\ln i - x + \ln i + x = \ln i-x * i + x$.

So what we get $\ln -1 - x^2$ which is $= \ln -1 + \ln 1 + x^2$, $\ln -1 -1$ lies on the real axis here okay. So the argument is π okay. So $\ln -1 = \ln e$ to the power $i\pi$ it is magnitude is 1 okay. Magnitude of -1 is 1, so this is $i\pi$, so what we get this is $= i\pi + \ln 1 + x^2$. So this + this okay is $\ln 1 + x^2 + i\pi$, so the right integral 0 to r, $\ln 1 + x^2/x^2 + 1 + \int_0^R i\pi/x^2 + 1 dx + \int_{\Gamma} \ln z + i/z^2 + 1 dz = \pi \ln 2 + i \pi^2/2$ okay.

(Refer Slide Time: 29:42)

As $R \rightarrow \infty$, the integral $\int_{\Gamma} \frac{\ln(z+i)}{z^2+1} dz \rightarrow 0$

hence taking the real part we find $\int_0^{\infty} \frac{\ln(x^2+1)}{x^2+1} dx = \pi \ln 2$

Handwritten notes:
 $\left| \frac{\ln(z+i)}{z^2+1} \right| = \frac{|\ln(z+i)|}{|z^2+1|}$
 $\leq \frac{\ln(R+1) + 2\pi}{|z|^2-1}$
 $= \frac{\ln(R+1) + 2\pi}{R^2-1}$ along Γ

as $R \rightarrow \infty$.

Handwritten notes:
 $\left| \int_{\Gamma} \frac{\ln(zei) dz}{z^2+1} \right| \leq \left(\frac{\ln(R+1) + 2\pi}{R^2-1} \right) \cdot \frac{2\pi R}{R+1} = \frac{2\pi R}{R+1} \frac{\ln(R+1) + 2\pi}{R-1} \rightarrow 0, \text{ as } R \rightarrow \infty$
 $|\ln(zei)| = |\ln|zei| + i \arg(zei)| \leq \ln(R+1) + 2\pi$
 $|zei| \leq |z+i| = R+1$
 $|zei| \leq |z-i| = |z+i| \leq |z| + |i| \leq |z| + 1 \leq |z| + |z| = 2|z|$

Now as R goes to infinity, as R goes to infinity these integral goes to 0, so what do we get integral over 0 to infinity $\ln x^2 + 1/x^2 + 1$ what do we get here. This becomes, this integral become 0 to infinity $\ln 1 + x^2/x^2 + 1 dx$ and this becomes integral/0 to infinity i we can write outside $\pi/x^2 + 1 dx$ and this is $0 = \pi \ln 2 + i \pi^2/2$, okay, so equating real parts both sides.

This is left side, we have this real part, so this real part = this real part okay and this imaginary part = this imaginary part. So you can see also the integral 0 to infinity $\pi/x^2 + 1 dx$ is $i \cdot \pi^2/2$ because this is π times integral 0 to infinity $1/x^2 + 1 dx$ which is $\pi/2$ okay. So we get $i \pi^2/2$, so this is = this and this is = this and what we get here integral 0 to infinity $\ln x^2 + 1/x^2 + 1 dx = \pi \ln 2$ as R goes to infinity.

Now let us show that integral over $\gamma \ln z + i$ over $z^2 + 1 dz$ goes to 0 as r goes to infinity. So let us find the modulus of $\ln z + i/z^2 + 1$, modulus of this. so this is mod of $\ln z + i$ /mod of $z^2 + 1$, this is \leq , this is mod of $z^2 - 1$ and $\ln z + i = \ln \text{mod of } z + i$ okay. Mod of $z + i + i$ times argument of $z + i$. Okay mod of $z + i$ is \leq mod of $z + \text{mod of } i$ okay.

So this is $R + 1$ okay, so this is $\leq \ln R + 1$ okay and here what we will get i times 2π because argument of $z + i$ cannot be more than 2π if we are considering principle value of the logarithm. So we get here $\ln R + 1 + 2\pi$. Magnitude of this, let us put magnitude of this and then here we can write, let us take mod of $\ln z + 1$. So mod of $\ln z + i$ is mod of \ln , mod of $z + i + i$ times argument of $z + i$.

$\text{Ln mod of } z + i \text{ is } \leq \ln R + 1$ and mod of this is \leq by triangle inequality mod of $\ln z + i +$
 argument of mod of argument of $z + i$, argument of $z + i$ cannot exceed 2π okay. So this
 actually we are using here triangle inequality. You can say we are using here this triangle
 inequality. Here we are using mod of $z_1 + z_2 \leq \text{mod of } z_1 + \text{mod of } z_2$, okay, so this is $\ln R$
 $+ 1 + 2\pi/R^2 - 1$ okay along gamma.

Now what we have, so mod of thus mod of $\ln \int_{\gamma} \frac{dz}{z^2 + 1}$, $\ln z + i$ $dz/z^2 + 1$, mod
 of this is $\leq \ln R + 1 + 2\pi/R^2 - 1 * \text{length of gamma}$ that is πR okay. Now we can
 write it as $\ln R + 1/R + 1 + 2\pi/R + 1 * \pi R/R - 1$ okay. When R goes to infinity $\pi R/R - 1$ goes
 to π okay. So this goes to π , now inside the bracket $2\pi/R + 1$ goes to 0 and $\ln R + 1/R + 1$ also
 goes to 0 because $\ln x/x$ goes to 0 when x goes to infinity.

So this goes to 0 as R goes to infinity. So this is how we show that this integral goes to 0 as R
 goes to infinity and thus the integral from 0 to infinity $\ln x^2 + 1/x^2 + 1 dx = \pi \ln 2$. So
 with this we come to the end of this lecture and we have finished the discussion on evaluation
 of real integrals using residue theorem. Thank you very much for your attention.
